Operating under the Social Security Administration, the Children's Bureau administers grants to states for maternal and child health, and crippled children's and child welfare services. This year grant money totals $39,361,000, divided as follows: $16,000,000 for maternal and child health work, with the states required to spend approximately 50 cents for each federal dollar, $15,000,000 for crippled children's services, same matching requirement; and $8,361,000 for child welfare services, where the only matching requirement is that states must supply some money. In addition the Children's Bureau has $1,822,000 to finance investigating and reporting activities and to administer the grants.

Food and Drug Administration.....................................$7,979,000

(Last year: $6,266,000)

For administering the federal Food, Drug, and Cosmetic Act, Congress voted $6,779,000, which includes $309,000 for policing the distribution of Salk poliomyelitis vaccine during this fiscal year. FDA will also realize an estimated $1,200,000 from fees paid by industry for certification of biologics, insulin, seafood, etc. The figure for last year does not include fees

Office of Vocational Rehabilitation............................$42,110,000

(Last year: $36,825,000)

Under the expanded Vocational Rehabilitation Act (Public Law 565, 83rd Congress) Congress this year voted $36,000,000 for grants to states. This is divided as follows: (a) support of basic rehabilitation services including medical examination, surgical and therapeutic treatment, hospitalization, prostheses, occupational tools and aids, vending stands, rehabilitation facilities, vocational training, and funds for maintenance (based on per capita income and populations as in Hill-Burton), $33,500,000; (b) extension and improvement of state programs, $1,500,000; (c) special grants to states or nonprofit organizations for projects designed to expand the rehabilitation program (2-1 federal-state matching), $1,000,000. In addition $2,950,000 is available for training of rehabilitation personnel, including physicians, therapists, psychologists, counselors, medical, and psychiatric social workers; $2,000,000 for grants to states and other public and nonprofit agencies and organizations to pay part of the cost of special research and demonstration projects in vocational rehabilitation; and $1,160,000 for federal administrative costs.

United States Office of Education.............. Approx. $2,545,000

(Last year: not reported)

Practical Nurse Training: For a goodly number of years the Office of Education has been making grants to states for vocational education in all fields of endeavor. It is estimated that during the last fiscal year approximately $500,000 in grants was used to educate practical nurses. For this year, the Office of Education has available $31,267,000 for grants to states. Included in this figure is $2,000,000 earmarked funds recently authorized by Congress (practical nurses). An appropriation was voted in this amount, plus an additional $45,000 for added costs of administration. Office of Education officials believe that the states will not diminish the level of last year's program, which would mean approximately $2,545,000 is available for practical nurse education.

FEDERAL CIVIL DEFENSE ADMINISTRATION

(This Year: $49,810,000—Last Year: $30,450,000)

Projected health and medical spending by FCDA this year moves close to the $50,000,000 mark for the first time. Out of a total appropriation of $93,560,000, the estimated $49,810,000 spending for the FCDA health office includes $47,000,000 for stockpiling medical and other supplies owned wholly by the federal government, $1,700,000 for matching funds to the states to help them in their medical stockpiling, $810,000 for research, and $300,000 for administration costs.

ATOMIC ENERGY COMMISSION

(This Year: $31,525,000—Last Year: $27,700,000)

The Atomic Energy Commission's Division of Biology and Medicine has about 2.7 million dollars more than last year for research projects. This year's total includes the following spending plans: cancer, $3,002,000; other medical, $9,729,000; biological, $10,821,000; biophysical, $3,459,000; development of new laboratory equipment, $2,319,000; vocational and special training, $615,000; radioisotope distribution, $510,000; and miscellaneous items, $1,070,000.

INTERNATIONAL COOPERATION ADMINISTRATION

(This Year: $29,310,000—Last Year: $25,441,000)

Technical Cooperation Programs....$16,380,000

(Last year: $20,141,000)

The International Cooperation Administration through direct contributions (which do not have to be matched dollar for dollar) is helping underdeveloped countries to control specific diseases, to set up national and local health services and to establish environmental sanitation. Countries receiving money make contributions in cash, facilities or services in varying degrees.

Development Assistance Programs....$12,930,000

(Last year: $ 5,300,000)

Spending for emergency health programs (particularly in malaria control on which there is new world-wide emphasis) under ICA direction is up from last year. The agency has $2,500,000 for the Far East, and $10,430,000 for the Near East, South Asia, and Africa. The largest single beneficiary will be India.

DEPARTMENT OF STATE

(This Year: $15,496,000—Last Year: $13,669,790)

United Nations Children's Fund....$9,700,000

(Last year: $9,000,000)

The United States' share of the Children's Fund is up about $700,000 over last year for a total of $9,700,000, but the percentage of the United States' contribution to the total fund has dropped slightly from 60 to 57.5. This is due to the fact that some of the 65 other nations contributing have increased their share slightly. The fund is aiding about 264 health and medical projects in 92 countries and territories, benefiting 32 million children and mothers. Last year the fund treated 1,800,000 children for yaws, vaccinated 14,500,000 against tuberculosis, and 9,000,000 against malaria and other insect-borne diseases.

World Health Organization....$3,410,000

(Last year: $3,349,790)

The United States' share of the WHO budget remains at one-third of the total of all member nation contributions. Among the 84 countries agreeing to make contributions is Russia, which until recently has been inactive. Last year WHO was sponsoring about 500 health projects in 106 countries and territories. WHO's over-all budget is broken down this way: approximately 72% for operating programs, 10% for administration and salaries, and the rest for such expenses as holding international conferences, and to compensate for nonpayment by inactive member countries.

Pan American Sanitary Bureau....$1,386,000

(Last year: $1,320,000)

The United States is contributing approximately two-thirds of the bureau's regular budget which this year totals $2,100,000. In addition, the United States plans an extra $1,500,000 for 1957 malaria eradication programs. Because these international groups operate on a calendar year, the special contribution is not shown in this report. The bureau, in existence many years before WHO was organized, is the regional office of WHO for the Americas. The bureau is sponsoring health programs in 21 Latin American countries and the United States.

Foreign Service Employees Medical Care....$1,000,000

(New category)

The 84th Congress, under Public Law 828, broadened an existing medical care program for foreign service employees to take in their dependents, provided they are living overseas. State Department, which estimates that about 15,000 dependents are involved, has earmarked $400,000 for the first year. The regular program for overseas employees is placed at $600,000. Most of the care is provided in United States military facilities.

FEDERAL EMPLOYEES HEALTH PROGRAM

(This Year: approx. $10,000,000—Last Year: approx. $6,000,000)

Another health program, this one available to all federal civilian workers, provides limited services through health clinics. They are operated by federal agencies that employ 300 or more persons in any one area. By regulation, maximum cost of a health service cannot exceed $11 a year per employee, although special industrial conditions or minimal size unit may warrant a higher ceiling. Services include treatment for on-the-job illnesses and physical examinations for employment.

NATIONAL SCIENCE FOUNDATION

(This Year: $8,000,000—Last Year: $5,000,000)

The foundation's over-all budget of $40,000,000 is two and a half times last year's appropriation. While money earmarked for research grants in biological and medical sciences this year does not show the same proportionate increase, it is still considerably above the fiscal year 1956. The foundation, now in its sixth year, initiates and supports basic scientific research, evaluates research of government agencies, and correlates research programs of various agencies.

DEPARTMENT OF LABOR

(This Year: $7,151,126—Last Year: $7,336,000)

Bureau of Employees' Compensation....$6,600,000

(Last year: $6,800,000)

An estimated 2,390,000 federal workers now are eligible under the Federal Employees' Compensation Act for medical and hospital care, rehabilitation services, disability and death payments, and funeral and burial expenses. For treatment of employees by private doctors and hospitalization in private facilities, Labor Department has set aside $4,500,000 this fiscal year, and for similar services in federal hospitals and clinics, $2,100,000. A slight shift is noted away from federal facilities to private resources; last year's totals were $4,349,218 and $2,234,222.

Bureau of Labor Standards....$551,126

(Last year: $536,000)

For promotion of industrial safety, the bureau plans to spend $387,322, and for reemployment programs of the physically handicapped, $163,804. The agency develops standards for hazardous occupations, assists the states in accident prevention programs and trains personnel for administering various projects.

The detection of carcinoma in patients with achalasia is particularly difficult in view of the fact that dysphagia has usually existed for some time and does not increase with the development of malignancy. One of the most characteristic signs is the presence of anemia and hematemesis. Another sign was a foul odor to the breath caused by necrosis of the tumor.

Chronic irritation is generally considered to be a factor in the production of malignancy. This irritation in the esophagus may be the result of chronic ulceration secondary to lye burns or peptic esophagitis associated with hiatal hernia, or it may be bacterial as a result of stasis and infection in patients with achalasia of the esophagus and diverticulum. Though malignancy does not develop in many patients with each of these conditions, it is unwise to allow any of these conditions to persist untreated when complicated by a significant esophagitis. The existence of this complication must be acknowledged, the proper examinations frequently made, and the indicated therapy provided to eliminate chronic esophagitis in order to prevent later malignancy. No examination is complete without examining the esophagus by x-ray (only after proper cleansing) and by the esophagoscope, with the help of which the mucous membrane may be directly visualized.

Kaliopenic Nephropathy. J. W. Conn and R. D. Johnson. Am. J. Clin. Nutrition 4:523-528 (Sept.-Oct.) 1956 [New York].

Conn and Johnson collect the available evidence that chronic hypokalemia, always associated with a significant deficit of body potassium (kaliopenia), results in characteristic anatomic and functional lesions of the renal tubules. This lesion exists in the newly described clinical syndrome called primary aldosteronism. Since in the latter condition chronic hypokalemia occurs in man via a mechanism that is unique and that differs from previously recognized causes of potassium depletion, demonstration of the typical pathological and functional lesions of the renal tubules seems to relate this condition to lack of the potassium ion. Kaliopenic nephropathy must be recognized as a clinical and pathological entity. It can be induced experimentally by diets deficient in potassium. It is reproducible by repeated administration of large doses of desoxycorticosterone and is preventable when supplementary potassium is given in such experiments with desoxycorticosterone. In man, the syndrome is observed most frequently in the potassium-deficient state associated with chronic intestinal disease. It is also present in primary aldosteronism, the renal manifestations of which are analogous to desoxycorticosterone-induced "diabetes insipidus" in animals. A decreased tubular capacity to reabsorb water, not influenced by administered pitressin, is the most distinctive functional abnormality encountered in kaliopenic nephropathy. While other renal functions, too, may be impaired, hyposthenuria is disproportionately severe. Histologically, the lesion is limited to tubular cells and is characterized by diffuse hydropic vacuolarization. This anatomic lesion is observed in chronic hypokalemia in man no matter whether it is produced by long-standing diarrhea or by an aldosterone-secreting cortical tumor. In most instances both the functional and anatomic abnormalities appear to be slowly reparable after replacement of the potassium deficit. It is likely, however, that in some cases so much damage has occurred during chronic kaliopenia that functional recovery is impossible.

Nutrition in Chronic Renal Failure. A. J. Merrill. Am. J. Clin. Nutrition 4:497-508 (Sept.-Oct.) 1956 [New York].

The management of nutrition in chronic renal failure differs from that in acute renal failure in several respects: 1. The duration of the disease requires that the diet be adequate in caloric, vitamin, mineral, and protein content and that it contain proper amounts of the essential amino acids. 2. The diet must be palatable, since tube feeding is impractical and undesirable for extended periods and because a tasty diet is essential to the morale of these patients whose appetite at best may be none too good. 3. Potassium intoxication is not so common as in acute renal failure, since the urine volume is usually ample except when the patient is moribund. 4. Fluid control is not so exacting as in acute renal failure, because the urine volume can adapt itself to the intake of fluids within variable limits. Chronic renal failure affecting chiefly the glomeruli produces problems of abnormal retention of substances, whereas chronic tubular disease produces deficits principally of cations. The latter is simpler to treat, although there is a lack of adaptability to either deficits or excesses.

Water intake should be high unless water retention or edema is present. Forcing fluids in the presence of edema will cause deterioration of renal function. The salt intake should average about 4 or 5 gm. daily; it should be reduced with water retention, but few patients will tolerate rigid restriction. Massive amounts of salt may be required in unusual instances. Potassium abnormalities are treated as indicated by the blood level and excretion studies. Patients with plasma potassium levels above 5.5 Meq per liter should be either watched very carefully or treated with a potassium-absorbing resin. Calcium deficiency without blood phosphorus elevation responds well to oral administration of calcium, vitamin D, and alkali administration (after milk-alkali administration, vitamin D intoxication, and hyperparathyroidism have been ruled out). If the blood phosphorus is high, these measures are futile and phosphorus has to be eliminated with aluminum hydroxide. The diet should contain about 0.5 gm. per kilogram of body weight of animal protein daily, supplied by a protein of high biological value, about 3 to 4 gm. per kilogram of carbohydrate and 1 to 1.5 gm. per kilogram of fat. In an addendum to this report the author presents a menu for a diet containing approximately 2,200 calories, 50 gm. of protein, and 4 gm. of salt.

SURGERY

Five-Year Postoperative Results of First 500 Patients with Blalock-Taussig Anastomosis for Pulmonary Stenosis or Atresia. B. D. White, D. G. McNamara, S. R. Bauersfeld and H. B. Taussig. Circulation 14:512-519 (Oct.) 1956 [New York].

Three hundred eighty-nine of the first 500 patients with a Blalock-Taussig anastomosis for pulmonary stenosis or atresia survived six months or longer after the operation. Sixty-seven of the 389 patients were lost to follow-up. Eleven patients who survived the operation were unimproved by their first operation. In an additional 67 patients a five-year follow-up was not completed at the time the authors' study was closed. Thus there remain 244 patients originally improved by a Blalock-Taussig anastomosis who have been followed up for five years or longer, of these, 226 obtained good results, i. e., their exercise tolerance was virtually normal and their hearts were stationary in size, with a cardiothoracic ratio of 60% or less. The hemograms were also stationary, with a maximum red blood cell count of 6,500,000, a maximum hemoglobin of 17 gm., and a maximum hematocrit reading of 55 volumes per 100 cc. Eighteen obtained fair results from the first anastomosis. The good results were maintained in 163 patients (67%) five to eight years after the operation, and in 16 patients (7%) the results were still fair after the lapse of time. Nine patients (4%) were no longer improved and 23, i. e., 9% of those originally improved, required and survived a second operation.

Thirty-three patients (14%) died between six months and eight years after the operation. A higher percentage of patients with tetralogy of Fallot maintained good results postoperatively than of those with other malformations of the heart, and the mortality rate was significantly lower in the former group. One hundred twenty-six of the 163 patients with good results who were evaluated for changes in cardiac size, changes in the hemogram, and, whenever possible, changes in the arterial oxygen saturation, were in excellent condition in all respects. Twenty-three of the 163 patients had considerable nonprogressive cardiac enlargement. Fourteen patients had moderate and nonprogressive polycythemia. In most of these patients a good continuous murmur, which indicates that some blood is flowing from the aorta to the lungs, was observed. The best results were obtained in children who were between the ages of 8 and 12 years at the time of the operation. Subacute bacterial endocarditis was diagnosed in 15 (6%) of the 244 patients in the late postoperative period. Twenty-three of the 226 patients who originally obtained good results died, a late mortality rate of 11%, whereas 8 (44%) of the 18 patients who had obtained only fair results died. Of the 33 patients who died, 19 were no longer improved, 6 were losing ground, and 8 were doing well at the time of death. No patients with a tetralogy of Fallot died of cardiac failure.

These findings suggest that the optimum age for operation is between 8 and 12 years; 80% of the patients in this age group maintained their improvement five to eight years after the operation. The risk of postoperative subacute bacterial endocarditis, although real, is not great. Patients in whom the red blood cell count remains below 6,500,000, the hemoglobin below 17 gm., and the hematocrit below 55 per 100 cc. have an excellent long-term prognosis. A patient with these findings who has a tetralogy of Fallot and a cardiothoracic ratio of 50% or less has a particularly favorable prognosis.

Arterial Disease as a Cause of Pain in the Buttock and Thigh. G. Bonney. J. Bone & Joint Surg. 38-B:686-691 (Aug.) 1956 [London, England].

When a patient attends an orthopedic clinic with the complaint of pain affecting the calf of the leg, the possibility of arterial disease as a cause of the pain is usually remembered, but, when the pain is in the buttock or thigh, that possibility is often overlooked. Ten patients are reported on in whom pain due to arterial obstruction simulated pain caused by bone or joint disease or by disorder of the intervertebral disk. All patients had been considered to be suffering from conditions such as osteoarthritis of the hip or lumbosacral disk degeneration and had received treatment accordingly. Mistakes in the diagnosis may not only lead to mistaken treatment but may also cause delay in giving correct treatment and may lessen the chances of success. The pain differs only in site, not in character, from that affecting the calf in classic intermittent claudication. Palpable tibial pulses do not exclude a diagnosis of vascular insufficiency in the lower limb. In three of the patients claudication was present with palpable tibial pulse. In all of these the tibial pulse became impalpable after exercise to the point of pain. Ischemic changes in the peripheral parts of the limb are not necessarily a feature in these cases of proximal arterial obstruction. Only 1 of the 10 patients had marked peripheral ischemic changes. Radiography, by showing calcification in the site of the great vessels, is often a useful pointer to the diagnosis. It is suggested that in orthopedic clinics, where attention is often directed largely to skeletal abnormalities seen on radiographs of the lumbar spine, closer search for evidence of aortic or iliac calcification might be rewarding. Aortography was performed in most of the 10 patients and revealed occlusion either at the aortic bifurcation or of the iliac vessels.

Cancer of the Breast, 1661 Patients: I. Considerations in Future Therapy. R. C. Hickey, H. D. Kerr, R. T. Tidrick, and others. A. M. A. Arch. Surg. 73:654-660 (Oct.) 1956 [Chicago].

This series of 1,661 patients with breast carcinoma represented the recorded patient material for 24 years at the University Hospitals, State University of Iowa. The standard therapy for breast cancer was radical mastectomy, which was employed in 913 operable cases. Supplemental roentgen therapy was given in some of these cases. At five years from diagnosis, the over-all survival rate among the 1,661 patients was 36.8%. The five-year survival rate among all the patients treated by radical mastectomy was 46.8%. The five-year survival rate was 68.7% when the axillary nodes were free of cancer at the time of operation and 33.1% when they showed involvement. Roentgen therapy offered no measurable benefit in terms of survival and pattern of first recurrence; in general, these cases were clinically more unfavorable. Recurrence was most frequent locally and in the axilla. Local recurrence is discouraging, because this area is presumably cleared by radical mastectomy. Even when recurrence was delayed for 10 years, it was frequently local. The author feels that this reflects the biological characteristic of breast cancer rather than poor surgery. Furthermore, the first appearance of a distant metastasis was unpredictable, in that it sometimes occurred early even in patients in whom the cancer was presumably limited to the breast. The classic radical mastectomy should not be abandoned as yet. Techniques should be improved, and patients to be treated by radical mastectomy should be selected more carefully. Superradical surgery should be considered as a clinical experiment. It is hoped that public education to facilitate early diagnosis and prompt surgical treatment will lead to better results.

Comparison of Radical and Less Extensive Surgery in Cancer of the Breast. W. C. White. Am. Surgeon 22:942-947 (Oct.) 1956 [Baltimore].

The author prefers radical mastectomy, which he performed in 290 patients, to less extensive surgery in cancer of the breast. There were three surgical deaths. Of 134 patients without axillary metastases, 107 or 80% were alive after five years, whereas, of 153 with axillary metastases, 48 or 31% were still alive after five years. The over-all five-year survival rate was 53%. Radical mastectomy had been accepted for many years as an excellent procedure, but some surgeons believe that the Halsted procedure is not extensive enough, while others maintain that it is needlessly extensive, and even harmful. Superradical surgery involves greater operative risk than the other methods, and is not based on a clear-cut anatomic and pathological consideration. McWhirter advocates simple mastectomy followed by sterilizing roentgen irradiation of the regional lymph nodes. With this treatment he obtained a crude five-year survival rate of 58%.

In spite of the apparently similar survival rates in his own and McWhirter's case material, the author still believes that the radical Halsted procedure is preferable to McWhirter's method, although he feels that there is need for improvement in the treatment of patients with axillary metastases. In addition to surgery, aid for these patients may take the form of x-ray therapy, hormonal gland excision, testosterone therapy, or perhaps one of the new chemical compounds.

Preservation of Rectum in Familial Polyposis of the Colon and Rectum. S. T. Coleman and C. Eckert. A. M. A. Arch. Surg. 73:635-644 (Oct.) 1956 [Chicago].

Thirteen patients with polyposis of the colon are presented. Several of the patients were related to one another and others had blood relatives with polyposis of the colon and rectum. Familial polyposis is usually progressive. New polyps form, and in any one of them cancer may evolve. Total colectomy with proctectomy is the only means of freeing the patient from the risk of cancer. A single surgical procedure cannot meet the requirements in all patients, because of the different clinical situations encountered and the difficulty of predicting the rate of progression.

The authors have continued to employ total colectomy and ileoproctostomy and thereafter to control any polyps that may form subsequently within the rectum by endoscopic removal and fulguration. Ileoproctostomy may be employed when there are no polyps within the rectum or their numbers are small, that is, when the greater part of the rectal mucosa is normal. Cancer of the rectum, large sessile polyps, or total involvement of the mucous membrane of the rectum are obvious contraindications to the preservation of the rectum. If ileoproctostomy is to be done, there must be assurance of cooperation on the part of the patient if the rectum is to be preserved in familial polyposis, because regular follow-up examinations must be carried out, with prompt removal of polyps as they appear. If the surgeon is doubtful about the patient's cooperation, preservation of the rectum should not be considered. There were no surgical deaths in the 13 patients, but one patient had intraperitoneal abscesses, and mechanical intestinal obstruction developed in 2 others. Intestinal function is excellent in 12 patients, but one patient has involuntary stools at night. Colectomy does not appear to retard growth or physical development when carried out in childhood.

NEUROLOGY & PSYCHIATRY

The Treatment of Tuberculous Meningitis. H. V. Smith and R. L. Vollum. Tubercle 37:301-320 (Oct.) 1956 [London, England].

Two hundred thirty consecutive unselected cases of tuberculous meningitis were treated at Oxford and observed for at least one year. The first 80 patients were treated with streptomycin alone, and the survival rate was 52%. The next 70 patients also received streptomycin, but in addition certain patients were treated with intrathecal injections of the purified protein derivalast 80 patients received intrathecal injections of purified protein derivative of tuberculin routinely, except when some special contraindication was present, and the survival rate rose to 75%. The use of purified protein derivative of tuberculin is potentially dangerous, as it must be given in sufficient doses to provoke a reaction, which consists in an abrupt though temporary worsening of the meningitis. The patient is pale and drowsy; he vomits and, if sufficiently conscious, complains of headache and pain in the back. The temperature and intracranial pressure, rise while the physical signs and mental changes become more marked. This clinical disturbance usually begins 8 to 12 hours after the injection of purified protein derivative of tuberculin and lasts 12 to 36 hours. The clinical disturbance is the price that must be paid for the meningeal reaction. Early in treatment the intensity of the clinical component tends to outstrip that of the cerebrospinal fluid component, but after a few reactions this relationship is reversed and brisk cerebrospinal fluid reactions can then be obtained at the cost of only a mild and transient clinical upset.

Measures designed to minimize the danger of the reaction are discussed. Cortisone has proved lifesaving in a few carefully selected cases. As, however, it is in many respects antagonistic to tuberculin, it has seldom been used with this treatment. It is concluded that intrathecal medication is still required for the optimal treatment of tuberculous meningitis; that purified protein derivative of tuberculin is a useful adjuvant to the chemotherapy; that these cases are best treated at special centers; and that, if the very advanced cases could be eliminated by earlier and more accurate diagnosis, recovery could be expected in approximately 100% of cases.

Pheochromocytoma and Electroconvulsive Therapy. F. R. Drake and F. G. Ebaugh. Am. J. Psychiat. 113:295-301 (Oct.) 1956 [Baltimore].

The authors present the history of a 34-year-old woman who died from cardiac arrest following electroconvulsive therapy. Autopsy revealed pheochromocytoma of the left adrenal. The case is presented so that other psychiatrists may become more aware of a tumor that can produce symptoms similar to those found in various anxiety states with or without depression. The diagnosis was particularly difficult, as no paroxysm of hypertension was ever detected. In addition, there was no sustained hypertension to arouse suspicion. Although a little atypical, the patient's signs and symptoms suggested a tension depression. Pheochromocytoma is an absolute contraindication to electroconvulsive therapy.

Tight Filum Terminale. P. H. Jones and J. G. Love. A. M. A. Arch. of Surg. 73:556-566 (Oct.) 1956 [Chicago].

A review of the records of 442 patients with spina bifida occulta seen at the Mayo Clinic in the past decade disclosed 6 with tight filum terminale. The histories of these patients, of whom four were children from 3 to 12 years of age and two were adults aged 35 and 34 years, are presented. Most of them had sphincteric and locomotive difficulties that began in childhood and were progressive. Difficulty with micturition was common. Three of the four children and one of the adults had enuresis or urgency of micturition, or both. The urinary difficulties of one patient were worse in the morning. Another child had retention with overflow; improvement occurred after severance of a taut filum terminale. All six patients had locomotive difficulties. One girl had to stop attendance at ballet classes because of increasing inability to perform fine movements. One woman walked with a limp of the right leg. Another had noted weakness and atrophy of the left leg since the age of 4 years. By the time she reached high school age, the weakness had increased and pain had appeared in the same leg. In the ensuing years, weakness progressed and numbness commenced. The pain was aggravated by coughing and sneezing. There was limping and stumbling when walking. One girl complained of difficulty in using the left leg and stiffness of the knees. A boy had clawing of the toes of the right foot and stiffness of the knees during the two years before admission.

Stigmas of spina bifida were present in five patients. Increased quantities of hair were noted in three, a fat pad in two, and a fovea sacralis in another. A meningocele was present in one child. Roentgenograms of the lumbar spine revealed spina bifida in each patient. A tight filum terminale must be differentiated from other congenital anomalies and tumors and degenerative and inflammatory diseases. When progression of symptoms is seemingly from childhood and is accentuated at puberty, an anchoring of the spinal cord by a tight filum terminale is a strong possibility, and any patient with symptoms and signs of a progressive lesion should be subjected to surgical exploration. In each of the six patients presented, an intradural lumbosacral exploration was made and the tight filum terminale was resected. The results of the operations were gratifying. Recovery seemed commensurate with the severity of the preoperative symptoms and signs.

Carbohydrate Metabolism and Nutritional State in Multiple Sclerosis. H. Droller and I. J. N. Powell. J. Chron. Dis. 4:283-291 (Sept.) 1956 [St. Louis].

Observations in the course of glucose tolerance tests and on pyruvic acid levels had suggested that a disturbance of the carbohydrate metabolism played a part in multiple sclerosis. The pyruvic acid levels were considered particularly important because they implied a thiamine deficiency. The diphosphate of thiamine (cocarboxylase) is required for the decarboxylation of pyruvate, and, in its absence, glucose oxidation stops at the pyruvic acid level. Pyruvate then accumulates in tissues and blood. An investigation was undertaken into the nutrition and carbohydrate metabolism of 10 patients with multiple sclerosis who subsisted on diets of their own choice. There were five men and five women. The general level of nutrition was poor, the intake of fat and protein was low in both sexes, and the carbohydrate intake was low in women. The thiamine and niacin of the diet appeared adequate. The observed patterns of abnormal glucose tolerance tests corresponded to those seen in starvation and could be rectified by glucose feeding. Diabetes was discovered in one of the patients after glucose feeding. There was no biochemical evidence of thiamine deficiency in these patients subsisting on poor diets, but temporary thiamine deficiency developed in one patient after extra loading with glucose. Glucose tolerance curves, following the administration of thiamine and cocarboxylase, respectively, were of similar pattern. Cocarboxylase and thiamine had no therapeutic value.

GYNECOLOGY & OBSTETRICS

Corticotropin in Severe Infections and in Postoperative Disease in Gynecology. P. Alfieri. Minerva ginec. 8:387-392 (May 15) 1956 (In Italian) [Turin, Italy].

Three patients with peritonitis, one with postembolic pneumonia, and two with postoperative syndrome were treated with small doses of corticotropin, 10 mg. every six to eight hours. Treatment lasted for from three to five days. The results were good and in some cases they were very good. There were no untoward side-effects. Antibiotics and vitamin C were combined with the hormonal treatment.

Ulcerative Colitis and Pregnancy. I. Macdougall. Lancet 2:641-643 (Sept. 29) 1956 [London, England].

This report concerns 100 pregnancies in 64 women among 398 patients (244 women and 154 men) with ulcerative colitis who attended the Gordon Hospital in eight years ending June 30, 1955. The ulcerative colitis began during or immediately after the pregnancy in 26 of the 64 women. A high proportion of these women had a severe form of ulcerative colitis. A quarter of all women with ulcerative colitis who had been pregnant had their first attack during either pregnancy or the puerperium. Inactive colitis was unaffected by pregnancy. Active colitis was improved in one-half, unaffected in a quarter, and aggravated in a quarter of the pregnancies. The proportion relapsing rises to a third when the puerperium is included in the time of onset of the ulcerative colitis. Successive pregnancies do not have a consistent effect on ulcerative colitis. The Ulcerative colitis does not adversely affect pregnancy. The most interesting feature of the behavior of ulcerative colitis complicated by pregnancy is the high proportion of women who experience a remission. In this a parallel could be drawn with rheumatoid arthritis, which responds to pregnancy in the same way. The link may be hormonal, for there is strong evidence that a large percentage of patients with ulcerative colitis give a good clinical response to treatment with either cortisone or corticotropin, and this is rather like the way the condition reacts to pregnancy.

The "Fern Test" of the Cervical Mucus as a Pregnancy Test. K. J. H. Verschoof. Nederl. tijdschr. geneesk. 100:2578-2583 (Sept. 8) 1956 (In Dutch) [Haarlem, Netherlands].

The formation of crystals in the dried mucus of the cervix uteri was first pointed out by Papanicolaou in 1946. The crystals appear in a palm-leaf or fern-leaf pattern during the follicular phase of the menstrual cycle, when the cervical mucus is watery, light, and transparent. The test has been variously designated as the crystallization, arborization, fern-leaf, or palm-leaf reaction of the cervical mucus. The uterine cervix, like the endometrium, undergoes cyclical changes. During the follicular phase (from the 5th to the 22nd day) of the cycle, under the influence of estrogenic substances, crystallization is evident in the dried cervical mucus, but after the corpus luteum forms, and the formation of progesterone becomes dominant, crystallization (fern-leaf) formation is inhibited and the fern test becomes negative. Now the dried mucus shows cells only and is devoid of crystals. The same is true during pregnancy, the dried mucus is cellular, showing no crystals. If crystals in fern-leaf arrangement are found in the cervical mucus, there is no pregnancy. Several case histories are presented that illustrate the value of the fern-leaf pregnancy test.

Transplacental Passage of Vitamins A, E, and D_2 Injected Intravenously in the Mother. R. Decio and V. Alamanni. Minerva ginec. 8:381-387 (May 15) 1956 (In Italian) [Turin, Italy].

Water-soluble preparations of vitamins A, E, and D_2 were administered intravenously to pregnant women. The quantities present in the blood of the mother and of the fetus were then measured. The values of vitamin A that passed into the fetus were of from 50 to 62.5%, the values of vitamin E were of from 88 to 100%. Values were of from 45 to 47% and of from 20 to 23% respectively when the two vitamins were given intramuscularly. The passage of vitamin D into the fetus could not be measured exactly; however, the authors advanced the hypothesis that it could reach values of 100%.

PEDIATRICS

Miliary and Meningeal Tuberculosis: Difficulties in Diagnosis. R. S. Illingworth. Lancet 2:646-649 (Sept. 29) 1956 [London, England].

Illingworth fears that the decline in the incidence of miliary and meningeal tuberculosis may lead to a lessened awareness of these conditions as possible causes of a child's illness. The early diagnosis of tuberculous meningitis is vital; for with early treatment one can guarantee a recovery rate of over 90% without sequelae, whereas, if the treatment is delayed until the child is unconscious, the risk of death or of serious consequences is greatly increased. The author describes some of the diagnostic difficulties in 236 cases under his care in the Children's Hospital, Sheffield. One hundred ninety-two of these children were admitted with meningitis and 43 with miliary tuberculosis (of whom 13 developed meningitis while in hospital). The following factors are listed as the chief causes of difficulties in the diagnosis of miliary and meningeal tuberculosis: 1. The vagueness of the initial symptoms: the commonest were tiredness, irritability, and loss of appetite. Nutrition may be good, and the child may be neither feverish nor drowsy. Headache and vomiting were usually late symptoms. 2. In 18% of the children there was a history of an injury or infection immediately before the onset of symptoms. 3. In 25% meningism was absent. 4. In 42% a tuberculin-jelly test was negative. The Mantoux reaction was also frequently negative; in some it gave a confusing delayed reaction. 5. In 14% the initial level of sugar in the cerebrospinal fluid was 50 mg. per 100 ml. or more. 6. In eight children the meningitis was both purulent and tuberculous. 7. In some cases, proved at autopsy to be miliary tuberculosis, nothing abnormal had been seen on x-ray examination.

The author suggests that a Mantoux test (1 in 1000), and not a tuberculin-jelly test, be carried out when tuberculous meningitis is suspected. Particular importance is attached to a positive result in a child recently exposed to tuberculosis, for meningitis is more likely to develop in the six months after exposure than at any other time; and a positive result in a child under 2 years of age should always be taken as signifying active tuberculosis. At the same time a lumbar puncture is done, and, though usually the cerebrospinal fluid sugar level is 10 to 40 mg. per 100 ml., there are occasional variations. By a proper technique, acid-fast bacilli will be found in the smear in 90% of cases of tuberculous meningitis, and in the remaining 10% the organism will eventually be demonstrated by culture and guinea pig inoculation. The chest is examined with x-rays with the knowledge that a normal roentgenogram does not exclude tuberculosis. The diagnosis is then weighed in the light of the history, the physical examination, and the special investigations.

Clinical Features of Children Suffering from Neurological Sequelae of Rh Iso-Sensitization. C. Burton-Bradley. Australasian Ann. Med. 5:203-213 (Aug.) 1956 [Sydney, Australia].

While investigating the obstetric and developmental histories of children who were brought to the Spastic Center, New South Wales, three mothers stated that their affected child had suffered from jaundice at birth. Arrangements were made with the Red Cross Blood Transfusion Service for Rh investigations to be carried out in all cases of cerebral palsy as a routine etiological investigation. Eighteen children are here reviewed, who were brought along with many other cerebral palsied children to the Spastic Center outpatient department in search of help. All presented with varying degrees of slowness in the acquisition of sitting, standing, walking, and speech. The ages at which these 18 patients were presented ranged from 8 months to 8 years. Fourteen of the 18 children with icterus gravis neonatorum had been given blood transfusions, and 4 had not. The present age range of the patients is 5 to 14 years. Athetosis, high-frequency deafness, hypoplasia of the enamel of deciduous teeth, defective upward eye motion, specific peculiarities of gait, and discrepancy between estimable intelligence quotient and learning capacity are features. Seventeen patients are athetoids. In electroencephalographic investigations, 13 patients have normal records, 1 is borderline normal, and 4 have abnormal reccords.

Complications Following Intravenous BCG Vaccination of New-Born Infants: Re-Examination Three and One Half Years After Vaccination. M. R. H. Stoppelman and E. F. Drion. Nederl. tijdschr. geneesk. 100:2584-2591 (Sept. 8) 1956 (In Dutch) [Haarlem, Netherlands].

Of 1949 children who had been vaccinated during the neonatal period by intracutaneous administration of BCG, 1,608 could be reexamined 3½ years later. The Mantoux test in a dilution of 1:100 was positive in from 87.5 to 98% of all children. On the basis of the method of vaccination, the children fell into three different groups. Those of group 1 received two injections of 0.1 ml. of BCG vaccine; those of group 2 received two injections of 0.05 ml.; and those of group 3 received two injections of 0.03 ml. Suppuration of the regional lymph nodes occurred in 26.6% of the children of group 1; in 7.1% of those of group 2; and in 3.1% of those of group 3. In many children suppuration of one or more of the regional lymph nodes began 10 months or longer after BCG vaccination. Six children showed enlargement and seven showed suppuration of the regional lymph nodes 3½ years after BCG vaccination. In five children pus was aspirated and examined bacteriologically, but no acid-fast bacteria were isolated. Statistically significant differences were observed with regard to frequency of complications as well as with regard to negative tuberculin reactions in children grouped together according to the date of vaccination. The cause of these differences cannot be definitely established, but it is pointed out that studies in France revealed that vaccines prepared on different dates by the same laboratory were of varying potencies.

Early Puberty Due to Granulosa Cell Tumor of the Ovary. J. Picañol. Rev. españ. pediat. 12:309-318 (May-June) 1956 (In Spanish) [Zaragoza, Spain].

Granulosa cell tumors of the ovary are relatively frequent in women but very rare in girls of the prepuberal age. A girl began to menstruate at the age of 6 years. After the third menstruation there was scanty bleeding for 10 days. The child was undersized and underweight. Her mental and skeletal development were retarded. The abdomen was distended, the breasts were slightly enlarged and the areolas were pigmented. A free hard tumor was palpable at the hypogastrium. The uterus was enlarged, as felt by rectal palpation. Vaginal smears showed folliculin modified cells. There were no symptoms of virilism. A laparotomy revealed a large ovarian cyst. The removed cystic ovary measured 10 by 8 cm. The cystic fluid contained granulosa cells with marked lutein differentiation. Treatment against hypothyroidism was established two weeks after the operation. Menstruation did not occur any more. The breasts diminished in size and the areolas lost their deep pigmentation. A follow-up of 15 months revealed the child to be in good condition. Her weight, size, and skeletal development have greatly improved.

UROLOGY

Radium Therapy of Malignant Tumors of the Bladder: New Technic and Results. R. Darget. J. Internat. Coll. Surgeons 26:435-439 (Oct.) 1956 [Chicago].

One hundred one patients with malignant tumor of the bladder were given radium therapy in France between 1942 and 1954. Twenty of the 101 patients had a tumor that did not invade the submucosa (type 1), 50 had an extensive tumor situated near the ureteral orifices (type 2), and 31 had very serious malignant lesions that had invaded one-third to one-half of the bladder, with involvement of the ureters and the renal pelves (type 3). A five-year cure was obtained in 16 and a three-year cure in 17 of the 20 patients with type 1 tumor. A five-year cure was obtained in 32 and a three-year cure in 34 of the 50 patients with type 2 tumor. Results were less satisfactory in the patients with type 3 tumor, but their prognosis was the least favorable one. A five-year cure was obtained in a total of 49 of the 101 patients and a three-year cure in 53. When a patient had survived three years he had the best chance of a permanent cure.

The results obtained do not conform to the concept of other workers that the efficacy of radium therapy is necessarily limited to "favorable cases," i. e., in patients in whom the tumor has not invaded the bladder wall. The procedure used by the author for the treatment of all three types of malignant tumor of the bladder is as follows: 1. The radium needles must be accurately placed; a wide cystostomy, therefore, is required. Before the needles are inserted, the tumor is leveled as deeply as possible with the aid of surgical diathermy. 2. The radium needles must be kept in place during the entire period of radium therapy. This is best accomplished by reducing the automatic contractions of the bladder with procaine hydrochloride infiltration of the nervi erigentes and the pudendal nerves before the operation. 3. A special rubber balloon filled with a saturated solution of lead nitrate is placed close to the needles; this device prevents the needles from moving and acts as a screen against irradiation. 4. The radium needles are left in place for three or four days, and the cystostomy is maintained for about four weeks before the bladder is closed. 5. Extraperitonealization of the bladder makes operating much easier in cases in which the tumor is deeply situated and is difficult to expose. Extraperitonealization permits intravesical and extravesical implantation of radium to be done simultaneously. The ureters are exposed at the level of the superior strait. If the tracts appear greatly enlarged and unhealthy, a bilateral cutaneous ureterostomy is performed and the ureters fixed side by side at the median line, which permits convenient collection of the urine. When the condition of the kidneys and the ureter remains doubtful, a simple ureterostomy is performed on each ureter and a plastic ureteral sound of sufficient caliber is inserted and is pushed up to the renal pelvis. This drainage is maintained until the exact condition of the kidneys and whether they are capable of improvement becomes known. The simple ureterostomy will then be replaced by either a cutaneous ureterostomy or a ureterointestinal anastomosis.

The Present Position of Radical Cystectomy in the Surgical Management of Carcinoma of the Urinary Bladder. V. F. Marshall and W. F. Whitmore Jr. J. Urol. 76:387-391 (Oct) 1956 [Baltimore].

About 200 radical cystectomies for cancer of the urinary bladder have been performed in the departments with which the authors are connected. This report is concerned with the first 100 patients, who were operated on more than four years ago. The term radical cystectomy, as employed in this paper, includes even pelvic exenteration, 53% of the patients actually having undergone exenteration. Of the first 100 patients undergoing radical cystectomy, 41 lived four years after their first symptom of bladder tumor and 19 lived four years after the operation. The survival of these patients as a group was far less than their calculated average actuarial expectancy. Only about 4% of patients with untreated bladder cancer of high grade and stage survived four years from the first symptom. The authors gained the impression that the survival rates after radiation of carcinoma in stages C and D were quite low—much less than after surgical therapy. They are of the opinion that radical total cystectomy is advisable when the following combination of circumstances exists: (1) the cancer has extended through the muscle layer but cannot be demonstrated, even by laparotomy and nodal dissection, to have metastasized (i. e., cancers in stage C); (2) at least part of the neoplasm is located in the basal or rectal half of the bladder; (3) the patient would appear to have a life expectancy of four or more years if the cancer were not present; and (4) adequate facilities are available. Other circumstances may also warrant the use of this radical technique; but the above combination appears the most clearly defined, and it has not been a rare combination in the experience of these authors.

THERAPEUTICS

The Effect of Chlorpromazine on Hepatic Function and Morphology. J. K. DeVore, C. Daugherty and E. M. Schneider. Gastroenterology 31:391-398 (Oct.) 1956 [Baltimore].

Laboratory and liver biopsy studies were made on 12 patients who were being treated with chlorpromazine. Eight of the patients had received chlorpromazine in daily doses of from [illegible] to 3,500 mg. for 183 days without showing signs of jaundice. Hepatic function tests and liver biopsies failed to reveal [illegible] striking changes or consistent pattern that might suggest [illegible] induced abnormalities. The four patients in whom jaundice [illegible] develop had received considerably less chlorpromazine [illegible] much shorter periods of time than the nonicteric group. Liver biopsy performed on three of the four subjects with jaundice revealed plugging of the bile canaliculi. In two instances [illegible] portal infiltration occurred, and in the third instance irregular reduction of intracellular glycogen was noted. Laboratory studies in all four subjects reflected no hepatocellular dysfunction. The most notable abnormalities were increases in total serum bilirubin and in the serum alkaline phosphatase. However, more striking than these changes noted during the acute phase of jaundice was the fact that in every instance the cholesterol ester fraction increased as the patient's jaundice decreased. This occurred despite the fact that in two of the four subjects a "normal" cholesterol ester–total cholesterol ratio existed throughout the period of icterus. The alkaline phosphatase–total cholesterol ratio was abnormally high in three of the four subjects and may be of value as an index for the early diagnosis of intrahepatic obstructive jaundice. It is interesting to note that the jaundice cleared rapidly in all subjects despite the continued administration of chlorpromazine. A majority of the cases of chlorpromazine jaundice reported in the American and British literature similarly showed no evidence of hepatocellular d ease but did reflect a picture of "intrahepatic obstruction." It is concluded that chlorpromazine is not a specific hepatotoxin but is capable of eliciting unpredictable hepatic responses in susceptible patients.

Cortisone Therapy in Hepatic Cirrhosis. L. Bárbera. Riforma med. 70:1086-1090 (Sept. 22) 1956 (In Italian) [Naples, Italy].

Nineteen patients with hepatic cirrhosis were treated with cortisone or prednisone. Five patients received cortisone by mouth in doses of 100 mg. per day for the first 10 days and of 75 mg. per day for the following days. Nine patients received prednisone by mouth in doses of 20 mg. per day for at least 30 days. The doses were always equally divided throughout the 24 hours. Except for some cardiotonic drug, no other substance was added to the cortisone or to the prednisone. Bilirubinemia diminished and diuresis increased. Extreme oliguria (150 to 200 cc. of urine per day) was converted into polyuria of up to 3,000 cc. of urine per day. The following results were observed: the total protidemia varied moderately; there was a tendency toward the correction of disprotidemia even in patients who showed a decrease of total protidemia caused by hormonal treatment; and albumin and beta globulin tended to increase and gamma globulin to decrease. A transitory improvement marked by the return of consciousness was observed twice in two patients with hepatic coma.

Acute Glomerulonephritis Treated with Prednisone. L. Bertoni. Riforma med. 70:1091-1094 (Sept. 22) 1956 (In Italian) [Naples, Italy].

The author reports on seven patients with glomerulonephritis treated with prednisone. Good results followed in six patients. A marked effect was obtained in patients with the disease in acute or initial stages. Clinical symptoms tended to disappear and the urine became normal; the course of the disease was shortened considerably. The results were negative in a patient with a subchronic form of glomerulonephritis. The author believes that the effect of prednisone is more antireactive than antiphlogistic. The danger presented by old cortisone drugs of increasing the retention of water and salt in patients whose kidneys are diseased has been overcome by new cortisone derivatives.

Hypertension Treated with Rauwolfia Canescens: A Comparison with Rauwolfia Serpentina. R. W. P. Achor and N. O. Hanson. New England J. Med. 255:646-650 (Oct. 4) 1956 [Boston].

The authors investigated by clinical trial whether Rauwolfia canescens possesses any advantages over R. serpentina in the treatment of essential hypertension. Nineteen patients were selected from those who had participated in a previous study in which R. serpentina (whole root) was compared with reserpine in the treatment of hypertension. All were ambulatory patients whose average blood pressure exceeded 165 mm. Hg systolic, 90 mm. Hg diastolic, during an observation period of three or more months before the study. There did not appear to be any striking differences between the effects of the whole-root preparation of R. canescens and those of a similar preparation of R. serpentina. This similarity of results pertained not only to effects on blood pressure and pulse rate but also to side-effects. If any difference existed, it was that R. canescens tended to have fewer and less severe side-effects. In particular, it seemed to have less sedative effect than R. serpentina. Depressive reactions that have been observed among hypertensive persons treated with preparations of R. serpentina are also associated with the use of R. canescens. Continued use of R. canescens was well tolerated over a period of eight or nine months, and only when the dosage was increased did more troublesome side-effects develop. In patients who initially obtained a satisfactory reduction of blood pressure—about 40% of those treated—it was possible to maintain this improvement even though the dose was cut by half and given once daily instead of twice. There was no evidence in this group of the development of "resistance" to the drug. Patients whose blood pressure was not lowered appreciably by the use of R. canescens in moderate doses did not respond significantly when the doses were increased by 50%. This suggests that, if there has not been a satisfactory reduction in blood pressure after two months of treatment with moderate doses of R. canescens, it is unlikely that an increase in the dose will result in further benefit. If a good reduction of blood pressure has been obtained, it seems reasonable to expect that decreased dosage of the drug may continue to maintain the good response as well as to lessen the frequency and severity of side-effects. R. canescens is a potent pharmacological agent whose use should be carefully supervised.

PUBLIC HEALTH

Human Exposures in Populated Areas During Airplane Application of Malathion. P. E. Caplan, D. Culver and W. C. Thielen. A. M. A. Arch. Indust. Health 14:326-332 (Oct.) 1956 [Chicago].

A joint study was undertaken during the summer of 1955 by the California State Department of Public Health and the U. S. Department of Agriculture to determine the feasibility of using aerial applications of malathion on populated areas to control adult mosquitoes. Because such applications would mean communitywide exposures to an organic phosphate insecticide, the magnitude of the exposure involved in this type of operation was investigated. Malathion was applied over the small community of Planada (population 1,500) in the Central Valley of California. The spray material, containing 7.5% technical malathion, 4% no. 40 motor oil, 22% Shell solvent no. 2, and 66.5% medium grade diesel oil, was applied at the rate of 0.46 lb. of malathion per acre from an altitude of 70 ft. It was discharged through no. 4 spray nozzles from a boom under the wing of a light airplane. Human exposure was measured by air-sampling and surface-deposit measurement techniques. These measurements were made in the open and inside buildings. The spray had a mass-median diameter of 109^{μ}. Comparison of air-sample measurements with surface-deposit measurements indicates that air sampling measured only 12% of the insecticide present in the outdoor atmosphere. This 12% probably represents inspiratory exposure. A man working in the open received an inspiratory exposure about five times greater than that of a man working inside a building. The outdoor skin exposure was roughly four times the indoor exposure. During the complete operation of airplane spraying of a small town, the total exposure of a man working outdoors was such that, when calculated on a milligram per kilogram basis, his inspiratory and skin exposures would have had to be multiplied by factors of 500,000 and 120,000, respectively, to approach $L.D._{50}$'s of experimental animals. On the basis of these findings, the application of malathion in amounts used in this study constitutes no hazard to the normal human population.

Antigenic Potency of Poliovirus Vaccines. S. Kelly and G. Dalldorf. Am. J. Hyg. 64:243-258 (Sept.) 1956 [Baltimore].

The commercial vaccines used in the state of New York during the summer and fall of 1955 were evaluated by Gard's method and the results related to other potency values, e. g., ratio value in the monkey potency test, and antigenic response in man. Some of the factors influencing estimates obtained by the test were also studied. Potency differences were detected varying from a few vaccines with no detectable potency to a few with high potency, with up to six-hundred-fold differences between these extremes. Many vaccines appeared to have greater type 3 than type 1 antigenicity. Vaccines potent by the guinea-pig test were also potent by the monkey test. The differences in potency apparent in the animal tests were not detected in a small-scale study of the serologic response of human beings to the vaccines. Factors found to influence potency values occurred chiefly in the neutralization test and included size of virus dose, choice of tissue-culture indicator, and length of observation period. Factors found to exert little or no effect on antibody production were animal weight and sex. Storage of serum at refrigerator temperature and in a frozen state before testing did not affect potency values. Vaccines stored for several months had potency values that were lower than previously estimated values. The authors also describe a simplified modification of Gard's test.

BOOK REVIEWS

Athletic Injuries: Prevention, Diagnosis and Treatment. By Augustus Thorndike, M.D., Chief Surgeon to Department of Hygiene and Department of Athletics, Harvard University, Boston. Fourth edition. Cloth. $4.50. Pp. 252, with 113 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1956.

The appearance of a new edition, the first in eight years, of this valuable work, originally published in 1936, coincides with greatly increased interest in the various medical aspects of athletics by physicians in the United States. The book has been so thoroughly revised that it is virtually new. Many of the excellent line drawings are new, and all of the illustrations are well done. The chapter on physical therapy has been entirely rewritten, and the one on physical fitness has been brought up to date. There is an ample bibliography drawn principally from American and English literature.

The first part is devoted to a discussion of the prevention of athletic injuries. It contains sections on the nature of and determination of physical fitness, including a discussion of the physiochemical changes and one on physical training. In discussing physical fatigue and aids in the prevention of injury, the author points out that the use of oxygen and various stimulants or "pep pills" has never been shown to improve athletic performance, whereas the abuse of these drugs may cause both physical and psychological harm. Part 2 discusses the common types of athletic injuries, and separate chapters are devoted to sprains, strains, contusions, fractures, dislocations, internal injuries, infections, inflammations, lacerations, and abrasions. The author points out that the description of a sprain should include accurate localization of the ligament involved, even though it may be necessary to revise this observation from day to day as treatment progresses. His finding that a sprain of the anterior tibiofibular ligament is the most common ankle sprain is at variance with other reports, but it appears to be based on careful, accurate observation. It is interesting to note that sprain of the tibial collateral ligament of the knee occurs four times as often as the next most common sprain. The discussion of muscle strains is excellent. Part 3 is devoted to the diagnosis and treatment of the more common regional injuries. It concludes with a chapter on physical therapy and reconditioning. The author finds that the bones most commonly broken are those of the fingers and hands, with those of the face a surprising second in incidence, preceding leg, wrist, and foot fractures. The facilities at the Harvard field house, which provide the opportunity to make roentgenograms and set simple fractures under anesthesia, make possible ideal early treatment for these serious athletic injuries.

There is room for some difference of opinion with regard to the value of the hypochlorite foot bath recommended for the prevention of epidermophytosis. The drop in incidence of this infection during the football season, cited by the author, could be due to the effect of physical training and improvement in general hygiene during this period. The use of 10% ammoniated mercury ointment and boric acid salve for the treatment of impetigo is probably outdated. Bursitis is discussed briefly, and no mention is made of x-ray therapy for this condition. Sprain of the sacroiliac joint is a questionable diagnosis when there are so many other possible causes of low back strain. The view that shin splints represent a muscle tear and that they must be treated by rest is at variance with the experience and practice of most runners and track coaches. The conclusions of the Kaplan-Browder study of prize fighters are not quoted fairly. These are only minor faults in an excellent and valuable reference book for any physician treating school, college, or professional athletes.

Speech Handicapped School Children. By Wendell Johnson, *Ph.D., Professor of Speech Pathology and Psychology,* University of Iowa, Iowa City, et al. Second edition. Cloth. $4.50. Pp. 575, with 8 illustrations. Harper & *Brothers,* 49 E. 33rd St., New York 16, 1956.

The book is a comprehensive survey of the speech disorders of children as seen from the standpoint of the educator. It is essentially a textbook for training teachers and speech therapists. The first two chapters present a general orientation and Johnson's point of view. The clinical point of view in education is stressed. The plea here is for increasing recognition in the school of all aspects of the child's development—physical, emotional, and educational—with particular attention to individual differences. Abundant statistical information is given to support the thesis that speech-handicapped children are an important part of the community. Therefore, they are worthy of a concerted effort on the part of the school personnel to correct the deficiency that so seriously interferes with communicative needs of such children. Each of the various types of speech disorders is dealt with in a separate chapter. A chapter contributed by S. F. Brown is devoted to the speech problems encountered in children with cleft palates and cerebral palsy. The aphasias are not considered. The longest chapter, reflecting Johnson's special interest, is devoted to stuttering. A chapter on the speech handicap of children with impaired hearing was contributed by Jacqueline Keaster, an audiologist.

Johnson's point of view toward children with speech disorders seems to be a useful one for teachers, and, as might be expected, the other contributors generally reflect the same point of view. Johnson is devoted to his subject and succeeds rather well in communicating his enthusiasm. In the chapter on stuttering, he dwells at length on the emotional aspects of stuttering, defines the disorder as a "type of anxiety-tension," and states that stuttering is an anticipatory apprehensive, hypertonic avoidance reaction. This point of view is probably useful for the educator, but, since the book does not include any analysis of therapeutic results, the reader is left with many unanswered questions. Johnson protests too much against the inclusion of stuttering in the category of neurotic symptoms. He devotes many pages to trying to protect his stutterers from the neurotic label. In this discussion he is not too successful and only manages to get involved in semantic arguments. This need not detract from the value of his contribution to education. Certainly it would be unfair to evaluate the book as a medical or psychiatric textbook, since this it is not and makes no claim to be.

The Labyrinth: Physiology and Functional Tests. By Joseph J. Fischer, M.D., Clinical Professor in Otolaryngology, School of Medicine, Tufts University, *Boston.* Cloth. $6. Pp. 206, with 30 illustrations. *Grune & Strat* Inc., 381 Fourth Ave., *New York* 16; 99 Great Russell St., London, W.C.1, England, 1956.

Knowledge about the labyrinth has increased in the last few decades to a scale unthinkable even a short time ago. From a viewpoint of function, the labyrinth is divided into cochlear and vestibulosemicircular parts and the study of each of these divisions has been developed into an advanced discipline. Although this book is entitled "The Labyrinth," it deals with facts and problems of only a small, nonacoustic part of this organ. Its real objective is to summarize the methods presently available for testing the vestibular apparatus. To help the reader understand the subject, the first chapter is devoted to a brief survey of vestibular physiology. The second chapter is concerned with the common vestibular symptoms and phenomena that are elucidated by the laws and theories of vestibular function. All vestibular reflexes and clinical signs, such as vertigo, nystagmus, and other spontaneous signs, and the induced reactions, such as past pointing, optokinetic reaction, calorization, rotation, and mechanical and galvanic reactions, are discussed and their origin explained. Chapter 3 is devoted to a presentation of the *functional* tests. The points, discussed from a physiological viewpoint in the previous chapter, are presented entirely from the

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

viewpoint of their clinical applications. The various methods of testing the vestibular apparatus are considered under the heading of Induced Reactions. This part of the book is comprehensive and modern in its concepts. The newer developments and modifications in the caloric and rotatory stimulation are presented and briefly explained. The techniques of performing these tests are given, and the evaluation of the findings is discussed. The reader can readily familiarize himself with the newest testing methods, for example, directional preponderance, culmination test, and cupulometry. Each section contains adequate references. At the end of the book is a survey evaluating the abnormal results of various test performances, and a differentiation is made between peripheral and central vestibular lesions. Vestibular testing and labyrinthine evaluation have never enjoyed their deserved popularity within the field of otolaryngology. This volume can be heartily recommended to physicians, from the first year otolaryngological resident, who should profit greatly from it, to the experienced practitioner.

Essential Urology. By Fletcher H. Colby, M.D., Consultant, Massachusetts General Hospital, Boston. Third edition. Cloth. $8. Pp. 656, with 358 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1956.

The fact that this third edition has been published within six years of the first attests to the author's ability to provide a text that keeps abreast of current diagnostic and therapeutic methods in urology. The book is divided into three parts. Part 1 deals with the embryology, anatomy, and physiology of the genitourinary organs; part 2 with examination of the urologic patient; and part 3 with diseases of the genitourinary organs. The first part is concise and factual. The development, adult relationships, and functions of the various organs are correlated so as to give a clear and accurate picture of the genitourinary system in health and disease. Drawings and photographs help to illustrate the subject matter. Where applicable, paragraphs called "practical considerations" point out salient facts that are clinically important. Part 2 is brief and touches on significant points in a patient's history and physical examination. Reference is made to a few laboratory tests as well as to cystoscopic and urographic studies. Part 3 constitutes about four-fifths of the volume. Beginning with the kidneys, each organ of the urinary tract is treated individually and consecutively. Each disease is introduced in broad general statements concerning the process. The lesions encountered are then reviewed, including both gross and microscopic features. Characteristic symptoms are considered and followed by the diagnostic methods that apply. Finally, treatment is reviewed and the prognosis outlined. In general, the subject matter is clearly and concisely presented in a readable fashion. Illustrative urograms and photographs demonstrating gross and microscopic pathology are used generously. In discussing topics on which multiple opinions or methods of management prevail, the author recognizes these differences and gives his own preferences. This edition should be of value, particularly to the medical student, the graduate student in urology, and the general practitioner. An extensive bibliography of current literature is provided.

New Bases of Electrocardiography. By Demetrio Sodi-Pallares, M.D., Chief of Department of Electrocardiography at National Institute of Cardiology of Mexico, Mexico City, with collaboration of Royall M. Calder, M.D., editor, English translation, Clinical Professor of Medicine, Graduate School, Baylor University, Houston, Texas. Translated from recent revision of third Spanish language edition, copyright by La Prensa médica mexicana, México 7, D.F. Cloth. $18.50. Pp. 727, with 523 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1956.

This English edition of a textbook on electrocardiography that has already had three Spanish editions is most welcome. The book is written primarily for students and incorporates within it the many years of teaching experience that the author has had at the National Institute of Cardiology of Mexico. For instance, one will find in this book the clearest explanation of the electrical position of the heart given anywhere. Although the author follows the lead of his teacher, the late Dr. Frank Wilson, he has also included results of his own research, particularly in reference to the correlation of electrocardiographic, clinical, and pathological data. The first chapters follow the conventional pattern of describing the electrophysiological basis for electrocardiography. Subsequent chapters are more concerned with the direct application of these principles than with the long detailed descriptions of clinical electrocardiography commonly found in most textbooks. Vectorcardiography, the ventricular gradient, and intracavitary potential are discussed thoroughly, each in separate chapters. The mathematics of electrocardiography is elaborated in an appendix. The text is well illustrated with diagrams and electrocardiograms. Although there is an excellent bibliography, a great deal of its effectiveness is lost because there is no correlation with the text. This book is recommended to the students and physicians who wish to learn the basic concepts of electrocardiography. No clearer presentation of these is available. It is also an excellent reference book for the cardiologist who from time to time needs a little refreshing in his field.

The Initial Management of Thoracic and Thoraco-Abdominal Trauma. By Lawrence M. Shefts, M.D., Thoracic Surgery Consultant to Brooke Army Hospital, Fort Sam Houston, Texas. Publication number 265, American Lecture Series, monograph in Bannerstone Division of American Lectures in Surgery. Edited by Michael E. DeBakey, M.D., Professor of Surgery and Chairman of Department of Surgery, Baylor University College of Medicine, Houston, Texas, and R. Glen Spurling, M.D., Clinical Professor of Surgery, University of Louisville, Louisville, Ky. Thoracic Surgery Division, editor: Brian B. Blades, M.D., Professor of Surgery, George Washington University, Washington, D. C. Cloth. $6.50. Pp. 121, with 18 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1956.

The background of this monograph is the experiences of the author during World War II. The author discusses resuscitation, thoracic wounds, thoracoabdominal wounds, wounds of the thoracic wall, and closed thoracic and thoracoabdominal trauma and includes illustrative cases. Resuscitation of the patient is foremost in the author's planned program of treatment. The pathogenesis, physiology, and pathological findings are emphasized. The author warns against panicky decisions and against stampedes to the operating room. As surgeons gained experience in the battle zone, fewer thoracotomies were performed. Technical considerations were intentionally omitted from the book. Preference was given to discussing the indications for, and the timing of, surgical operations. The illustrations and line drawings are well placed, graphic and clear and carry easily understood legends. The bibliography is up-to-date and authoritative. The illustrative cases are unusually illuminating; they represent each type of injury discussed in the monograph. With the increases in automotive travel and in the power and speed of vehicles, the number of severe injuries is increasing. This timely monograph is recommended for all physicians, particularly those who serve in the emergency rooms of hospitals.

Principles and Methods of Sterilization. By John J. Perkins, M.S., Director of Research, American Sterilizer Company, Erie, Pa. Cloth. $8. Pp. 340, with 174 illustrations. Charles C Thomas, Publisher, 301-327 East Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1956.

This volume was written to help persons who are responsible for sterilization in hospitals, but it could serve as a general guide for sterilization techniques. It integrates basic principles with practical methods for sterilization of materials. The principles and methods discussed, however, will also be of interest to physicians and surgeons, clinical instructors, pathologists, bacteriologists, and laboratory technicians. The first chapters contain a brief historical introduction and much of the basic material on sterilization and on the equipment used. Subsequent chapters deal with the practical aspects of sterilizing dressings, dry goods, rubber goods, surgical instruments, syringes, and needles. Various methods of disinfection and sterilization and their limitations are discussed, including the use of steam, dry heat, boiling water, chemicals, and gases. In other chapters are discussions on control techniques, central supply departments for hospitals, and preparation of parenteral solutions and infant formulas. References are included at the end of each chapter, and the book also contains a general subject index. The volume should be a valuable addition to the library of any person responsible for sterilization.

QUERIES AND MINOR NOTES

ATHEROSCLEROSIS

To the Editor:—*Please discuss the relative values of products containing choline, methionine, inositol, and Cytellin in the treatment of atherosclerosis and arteriosclerosis. What clinical proof is there showing the value of treating hypercholesteremia for preventing atherosclerosis and arteriosclerosis?*

Harry G. Kurz, M.D., La Habra, Calif.

Answer.—Choline, methionine, and inositol added to a normal, adequate diet are without effect on hypercholesteremia both experimentally in animals and clinically. They are equally ineffective in preventing cholesterol-induced atherosclerosis in animals. The sitosterols, like Cytellin, if given in large doses are capable of reducing cholesterol-induced hypercholesteremia and atherogenesis. Clinically they are useful in decreasing hypercholesteremia and in slightly depressing normal cholesterol levels. The effect, however, is not uniform in all patients so treated, some reacting more favorably than others. Generally, the higher the cholesterol level, the more pronounced the effect. At the present time there is no direct clinical proof that depressing hypercholesteremia helps to prevent the development of atherosclerosis. The justification for the use of these agents lies in the well-documented fact that diseases accompanied by hypercholesteremic states have a significantly higher incidence of atherosclerosis, particularly of the coronary vessels, than diseases accompanied by normocholesteremic states. Also, patients with coronary artery diseases, as a group, have elevated serum lipid levels. It is theoretically sound (and experimentally proved) to implicate the serum lipids in atherogenesis and therefore to try to reduce abnormally high serum lipid levels by dietary or pharmacological means in the hope of retarding the vascular process.

ULCER PILLS

To the Editor:—*Please give information on Exul, which is used to heal ulcers.*

M.D., Illinois.

Answer.—Exul is labeled to be a mixture of nupra (nonhormonic, nonsteriadic extract of cattle organs—liver, brains, adrenals, etc.), 2 gm.; dehydrated milk and cream, 15 gm.; choline hydrochloride, 30 mg.; ascorbic acid, 5 mg.; niacinamide, 1.2 mg.; thiamine hydrochloride, 0.6 mg.; vitamin B_{12}, 0.0009 mg.; and ferrous gluconate, 0.009 gm., with flavor of cocoa, milk solids, and sucrose added.

RICKETS WITH SO-CALLED ADEQUATE DIET

To the Editor:—*Is it possible to develop rickets despite prenatal calcium supplements, large amounts of milk throughout the first two years, and adequate doses of vitamin supplements in infancy? Is there any way, at this time, of definitely proving by x-ray or other means the presence or absence of rickets now or then?*

M.D., New York.

Answer.—It should be emphasized that rickets has now become a rare disease in the United States. During the early part of the century, most cases of marked knock knees were thought to be due to rickets. Now the burden of proof would be on anyone ascribing knock knees and other bone deformities to rickets. In any case the diagnosis of rickets should never be made on the basis of bone deformities alone. Genu valgum may be the result of numerous causative agents, and in most instances hereditary factors are responsible. Mild knock knee is commonly seen in young children and is considered physiological. Marked genu valgum may occur in patients with eccentro-osteochondrodysplasia (Morquio's disease), lipochondrodystrophy (Hurler's syndrome), or various forms of rickets; after poliomyelitis; or as a result of trauma to the lateral femoral epiphysis or the proximal tibial epiphysis. Thus accurate differential diagnostic studies must be carried out. To answer the first question specifically: a normal infant would never develop rickets on adequate prenatal and postnatal diets. There are, however, some forms of rickets that develop in spite of so-called adequate diets. These are vitamin D-resistant rickets (Albright), osteodystrophy (renal rickets), the Fanconi syndrome, celiac rickets, and cystinosis. All these conditions are usually associated with dwarfism and present other signs and blood disturbances that make their diagnosis possible.

In answer to the second question, the presence of rickets if still active could be definitely proved by the laboratory findings of low serum phosphorus level, normal or low serum calcium levels, and increased alkaline phosphatase. The x-ray manifestations at the wrist and knee would be very typical, with cupping, fraying, and flaring seen at the ends of the bone. Recently healed rickets would show the new deposits of calcium at the end of the bones, but the blood findings would be normal.

DIABETIC RETINOPATHY

To the Editor:—*Please discuss the relation of high-animal-protein diet, Propadrine, and vitamin B_{12} in diabetic retinopathy.*

Frederick E. Mott, M.D., New Haven, Conn.

Answer.—It is well known that the serum albumin level tends to be low and the beta globulin fraction frequently high in diabetes, particularly in patients whose glycosuria is poorly controlled and in those suffering from retinopathy and nephritis. It has been reported that, among a group of adequately treated diabetic patients with abnormally low levels of serum albumin, several exhibited an increase in these levels some weeks or months after the ingestion of a diet containing 120 to 140 gm. of protein daily. All of these are said to have experienced remission of retinopathy as judged by improvement in visual fields and visual acuity and cessation of hemorrhages. The implication that the return of serum albumin toward normal levels, occasioned by the high-protein diet, was responsible for the retinal improvement may be justified, and certainly the administration of such a diet, in the absence of renal failure, would be harmless. On the other hand, it must be recognized that the etiology of diabetic retinopathy is still unknown, and it has not been proved to be caused by low concentrations of serum proteins. Furthermore, because of the frequency of spontaneous remissions in the retinal lesions, it is very difficult to be certain whether improved visual acuity and cessation of hemorrhages are in fact attributable to the treatment employed. Perhaps the high-protein diet should be regarded as a means of attempting to correct low levels of serum albumin rather than as a treatment for retinopathy itself. Propadrine is a vasoconstrictor and bronchial dilator and would not be expected to be beneficial in diabetic retinopathy. Becker and co-workers have found that, after receiving a test dose of vitamin B_{12}, diabetics with retinopathy excrete nearly five times as much of the vitamin as do diabetics without retinopathy and approximately twice as much as nondiabetics. These observations should be regarded for the present as uncovering an interesting and possibly significant anomaly of vitamin B_{12} metabolism in such patients, but they do not demonstrate that treatment with vitamin B_{12} is beneficial. This has not been convincingly shown by any investigations to date. The medical management of this condition continues to be most unsatisfactory, except for measures aimed at the strict control of hyperglycemia and glycosuria, and even these are frequently unsuccessful.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

SEDATIVE ACTION OF ALCOHOLIC BEVERAGES

To the Editor:—*Could you give information on the sedative action of liquors (i. e., whisky, rum, vodka)? For example, would it be correct to say that a jigger of whisky might have the same effect as ½ grain (30 mg.) of any of the barbiturates?*

Royal A. Meyers, M.D., Watertown, Conn.

Answer.—The sedative action of an alcoholic beverage does not depend on the flavor of the drink but on the amount of alcohol consumed. Although the sedative effect of alcohol somewhat resembles the action of barbiturates and when both are consumed a definite synergistic effect occurs, it would be a mistake to consider their effects to be identical. Measurable effects of alcohol occur when the alcohol in two ordinary drinks (about 30 gm. of absolute alcohol) has accumulated in the body of an average-sized (150 lb. [68 kg.]) individual. The chief objective symptoms would then be measurable loss of judgment and deterioration of vision. Barbiturates produce their threshold effects of moderate narcosis with about 30 mg. (½ grain). The ratio of the weight of alcohol to the weight of barbiturates for threshold effects would then be about 1,000 to 1. When fatal dosages of alcohol and barbiturates are compared, this ratio is about 100 to 1. This approximation is arrived at by comparing a fatal dose of accumulated alcohol of about 320 gm. (400 cc., or the alcohol in 26 ordinary drinks) to the fatal dose of barbiturates—about 3.3 gm., or 50 grains.

OSTEOMYELITIS

To the Editor:—*A patient has had osteomyelitis of the right femur since he was 7 years old and he is now 46 years old. He has been operated on seven or eight times, the last operation having been performed on May 9, 1956. The infection extends into the distal end of the femur, and there is always a small amount of foul-smelling drainage from the wound. Since it is necessary to take medicine for relief of pain in the leg at intervals every day, he is considering amputation. Is there any possibility of bone grafting where approximately three-fourths of the femur would have to be removed? The upper one-fourth of the femur is not involved in the process.*

Howard V. Weems, M.D., Sebring, Fla.

Answer.—In osteomyelitis, resection of the femur and replacement by bone graft is not very satisfactory. Such grafts can be resorted to for filling old osteomyelitis cavities, if the infection can be brought under control. They will prove successful very often, but the success depends on whether there is enough soft tissue to cover the cavity adequately. The difficulties encountered in a case of this sort might be so great that amputation would be indicated, but such decision would depend on many factors, such as the type of organism causing the trouble, whether the organism is responsive to any of the antibiotics, and the amount of soft-tissue scar.

HISTOPLASMIN SKIN TESTS

To the Editor:—*In case of a positive histoplasmin skin test, what is the chance of false-positive reaction (1) in persons with negative skin tests for other fungi (coccioidin or blastomycin) or (2) in persons with positive tests for other fungi? Does the negative serology for histoplasmosis in the presence of a positive histoplasmin skin test and clinical evidence of obscure pulmonary disease of unexplained lymphadenopathy exclude (1) histoplasmin infection or (2) active stage of histoplasmosis? Please discuss the comparative value of the following serologic reactions in the diagnosis of active histoplasmosis: (1) complement fixation, (2) precipitin test, (3) agglutination, and (4) collodion agglutination.*

M.D., Ohio.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Histoplasma infections may result in skin-test sensitivity to other fungus antigens. Occasionally an individual may react strongly to histoplasmin but to a much lesser degree to blastomycin, usually less than 50% of the histoplasmin reaction, and coccidioidin rarely. A false-positive reaction to histoplasmin does not occur in persons with negative skin tests for other antigens. In persons with positive tests to other fungi as well, sensitivity to the homologous antigen, histoplasmin, is much greater than to the other antigens; therefore, the positive test becomes significant and is not to be considered a false-positive reaction. Thus it is wise to test for comparative purposes all three antigens: histoplasmin, coccidioidin, blastomycin (and also tuberculin, which does not produce cross reactions) at the same time. Negative serology, particularly the complement-fixation test, in the presence of a positive skin test for histoplasmin and clinical evidence of obscure pulmonary disease and unexplained lymphadenopathy could mean (1) that it might have been too early for antibodies to have formed, (2) that dissemination was occurring and antibodies had disappeared, or (3) that the positive skin test and the clinical condition were unrelated, that is, the positive skin test represented a mild or healed primary infection in the presence of some other disease. In the latter case, in all probability active histoplasmosis was not present. It must be remembered that the complement-fixation test is negative in about 10% of patients with active histoplasmosis and that about 8% of normal individuals have antibodies in low dilution. Serial complement-fixation tests should be done, as a change from a negative to a positive would be significant.

The complement-fixation test is the most valuable and practical serologic test for the diagnosis of active histoplasmosis. Serial tests should be made. In active infection, a rise in antibodies occurs with a peak during the second and third week of the disease and a gradual falling off at four to eight months. A low antibody titer early in the course of the disease may signify a poor prognosis (dissemination) and a high titer a self-limited disease with a good prognosis. In mild cases, the rise in titer is transitory, and, in more severe cases, antibodies may persist for a long time. Antibodies are absent or negligible in serums of patients with apparently only cutaneous or mucocutaneous lesions. Cross reactions rarely occur with an antigen of Coccidioides immitis in the complement-fixation test but not uncommonly occur with Blastomyces dermatitidis. However, in the latter, the complement-fixation titer rises with progression and remains elevated throughout the terminal stages; on the other hand, in focal lesions and cutaneous infections, the complement-fixation titers are low or absent. Precipitin and collodion agglutination tests are sometimes positive in milder cases in which complement-fixation antibodies have not developed. Because these tests may become negative in cases of long duration and because they are sometimes positive in early ones, regardless of whether coccidioidin, histoplasmin, or blastomycin is employed, some workers use all three tests in their laboratory in order to get the most information.

Answer.—The skin-test antigens (histoplasmin, blastomycin, coccidioidin, and haplosporangin) manifest varying degrees of cross reaction. Furthermore, the antigens currently in use have not been truly standardized, either against a homologous standard or against comparative standards. Therefore, comparison of test findings from other sources and their interpretation in relation to a given clinical case is not permissible on the basis of present-day information. The answer is "no" to both parts of the second question. Various types of serologic findings have been observed in known cases of histoplasmosis: (1) no detectable antibodies and (2) antibody dynamics with a rise and fall in titer during acute illness and the convalescent period. In some instances, the titer may wane but persist at low levels for years, while in the majority it tends to fall and disappear in about six months or so after the onset of infection. Patients with chronic pulmonary cavitary histoplasmosis are more likely to have prolonged persistence of detectable complement-fixing antibodies. On the other hand, tests on serums from some 50% of patients with disseminated histoplasmosis have been consistently negative. It should be apparent, then, that negative results with presently available serologic tests cannot be used to exclude prior or active infection with Histoplasma capsulatum.

There is much disagreement as to the value and accuracy of the serologic reactions in the diagnosis of active histoplasmosis. At present, complement-fixation tests with *yeast-phase antigens* appear to offer the most consistent results in tests on serums from experimentally infected animals. However, there have been no large-scale comparative studies involving all four types of tests listed. There are serious discrepancies in findings with different forms of antigen, for example, between yeast-phase and mycelial filtrate (histoplasmin) antigens in complement-fixation tests on the same serums. The picture is further confused by the cross reactions of serums positive for H. capsulatum with other fungus antigens and vice versa. In addition, the lack of standardization and uniformity of techniques among the various workers makes comparison of results relatively meaningless at present. It appears reasonable to conclude, however, that the detection of an antibody response with a "standardized" Histoplasma complement-fixation technique may, at least, permit the clinician to draw the diagnostic inference that the patient has been infected with one of a group of fungi that elaborate a common antigen. It should be emphasized, as indicated above, that failure to detect such an antibody response does not exclude fungal infection. Thus, demonstration of characteristic yeast forms in sections of biopsy material and/or isolation and identification of the organism remain the only certain means of establishing the specific diagnosis of histoplasmosis.

LOSS OF WEIGHT

To the Editor:—*Is there any drug or compound that will cause a loss of excess weight without the need of a strict diet? I am aware of the amphetamine compounds to lessen the appetite, but I would like to know of something else to use for this problem.* *T. J. Bluechel, M.D., Surfside, Calif.*

Answer:—No known drug or compound may safely be taken to cause loss of weight. The word safely deserves emphasis, since some drugs such as alphadinitrophenol, which have succeeded in taking off pounds, have had the disadvantage of making some people blind and killing others. Various diets have been suggested for obesity, including one comprised largely of protein, another comprised largely of fat, and one comprised largely of carbohydrate. There is no evidence that any one of these diets, or any other treatment of any kind, avoids the basic laws of energy exchange. In other words, all fat comes from food, and the only way an obese individual can lose weight is by eating less and exercising more. In this answer the more important question is not mentioned: What is it in an individual's life and make-up that gives him the appetite to cause obesity?

ALLERGY ASSOCIATED WITH MENSTRUATION

To the Editor:—*Please give information on the occurrence of allergic phenomena associated with menstruation. A patient aged 33 has urticaria (hives) with menses.*

Robert Z. Collings Jr., M.D., Casa Grande, Ariz.

Answer.—Allergic reactions such as skin diseases, asthma, and hay fever frequently occur in the premenstrual period and are usually associated with symptoms of premenstrual tension. Several theories concern the etiology of this condition. One of them postulates that the symptoms of premenstrual tension are the result of changes in the electrolyte and water balance of various tissues of the body, which are probably the result of cyclic ovarian activity. According to Zondek and Bromberg (*J. Obst. & Gynaec. Brit. Emp.* 54:1, 1947), allergic hypersensitivity to the steroid hormones or to the products of their metabolism excreted in the urine can be shown in certain pathological conditions generally related to menstruation or to the menopause by means of active cutaneous tests. Steroid hormones (estrogen, estradiol, progesterone, pregnandiol, testosterone, androsterone, and corticosterone), as well as prolan (chorionic gonadotropin) and insulin, were found capable of allergenic activity. The clinical manifestations of endocrine allergy can be the same, although the hormonal allergen may vary in different cases.

The following varied range of clinical manifestations may be due to endocrine allergy, though they need not necessarily be of this origin: (1) in the respiratory tract—asthma and vasomotor rhinitis; (2) in the cutaneous system—angioneurotic edema, chronic urticaria, and acne; (3) in the nervous system—migraine; (4) in the genital system—premenstrual tension and pruritus vulvae; (5) in the digestive system—nausea, vomiting, diarrhea, and epigastric pain during the premenstrual phase; and (6) in the ocular system—chronic recurrent conjunctivitis and certain forms of keratitis. Heckel (*Am. J. Obst. & Gynec.* 66:1297, 1953) states that the results of pregnanediol therapy tend to support the hypothesis that many disorders related to ovarian function—premenstrual distress, menopausal symptoms, ovarian pain syndrome (congestion-fibrosis syndrome, pelvic hyperemic syndrome), painful breasts and chronic cystic mastitis, some endometriosis and hypogonadism, and headache and dermatoses associated with the menstrual cycle—are caused by endogenous allergy to steroid hormones. Patients with these disorders were found to be sensitive to pregnanediol, a metabolic product of progesterone with no known biological activity. Pregnanediol produced systemic reactions resembling those already experienced, as well as local reactions to large doses.

LENSES FOR PATIENT WITH DEGENERATION OF MACULA LUTEA

To the Editor:—*A 29-year-old white man has complete degeneration of the macula lutea. The peripheral vision in both eyes is normal. Placental implants have been surgically placed in both retinas, with the hope of staying the progression of the degeneration in the macula area to the periphery of the retina. Is there some place in the United States that is able to make glasses for reading for such a patient? Clinical vision is 20/300 bilateral.*

Paul W. Hughes, M.D., Fort Lauderdale, Fla.

Answer.—It is not necessary for your patient to be sent to a special place in the United States for testing to see whether he can be helped. Magnifying lenses and devices offer the only means of making your patient able to read. Such devices and lenses are available to everybody through the American Foundation for the Blind, Inc., 15 W. 16th St., New York 11. They will send you on request their booklet of devices for helping such patients, and you can make the test yourself in your office. However, it is not at all predictable whether a person with 20/300 vision can be helped. These cases are individual, and one must make the tests rather than predict an outcome.

INGROWN TOENAIL

To the Editor:—*A woman is troubled with ingrown toenails on both great toes. Two years ago a surgeon removed the medial half of each nail, but the nails grew back and turned in as much as before, or more. Today she has much tenderness, pain, and discomfort, so that she is unable to walk any distance, nor can she wear heels that throw her weight on the great toe. Kindly advise if any operation has been devised that will give permanent relief for ingrown toenails.*

M. D., New Jersey.

Answer.—To prevent the recurrence of an ingrowing toenail, it is necessary not only to remove a section of the nail but to completely eradicate the nail bed of that section. The technique for this procedure has been described by several authors: "Diseases of the Foot," by Emil D. W. Hauser (Philadelphia, W. B. Saunders Company, 1950); "The Foot and Ankle: Their Injuries, Diseases, Deformities and Disabilities," by Philip Lewin (Philadelphia, Lea & Febiger, 1947); and "Functional Disorders of the Foot: Their Diagnosis and Treatment," by Frank D. Dickson and Rex L. Dively (Philadelphia, J. B. Lippincott Company, 1939).

CESAREAN SECTION IN PATIENT GIVEN PENTOTHAL

To the Editor:—*I would like to add to the answer given to the Query and Minor Note entitled "Cesarean Section in Patient Given Pentothal" in* The Journal, *Oct. 13, 1956, page 698, a reference to the report by Martland and Martland* (Am. J. Surg. *80:270, 1950). These authors showed that instead of a placental barrier there is a pooling tendency in the fetus for most of the sedatives given the mother by the oral, rectal, parenteral, or inhalation route. By actual analysis the barbiturates, for example, were found to accumulate in the fetus to a level almost twice that present in the mother, because of the slower and less efficient detoxification and excretory mechanisms of the fetus.*

Salk Vaccinations Urged for Holidays • •
Congressional Interest in Jenkins-Keogh Bills • •
Army, Air Force Report on Residencies • •
First Small Business Loans to Hospitals • •
VA Studying Tuberculosis Infection • •
Cancer Research Training Grants Made • •

POLIOMYELITIS VACCINE

Two more developments at the federal level have stressed anew the problems in the Salk poliomyelitis vaccine situation. The Public Health Service now estimates a manufacturers' backlog of close to 23,000,000 cc. of the vaccine, as well as uncounted millions in the hands of pharmacists and physicians. Secretary Folsom of the Department of Health, Education, and Welfare has blamed "public apathy" for the lag in the program.

Only four states have used up their grants from an original federal fund of $53,600,000 to help states in providing free vaccine to persons under age 20. They are Illinois, Kansas, North Dakota, and Vermont. Two others, Massachusetts and Rhode Island, have used all but a few dollars of their grants.

With this background, PHS Surgeon General Leroy Burney suggested families use the holiday season to arrange for inoculations for all persons under 40 years of age who have not had three injections. "Vaccine protection of unprotected children may mean that some will be around happy and well at future Christmases who otherwise may be crippled or killed by polio. And parents and others under 40 years of age should arrange their own protection. I personally have seen instances in which both parents in an age span between 22 and 25 years have been stricken and one or both crippled for life," Dr. Burney declared.

In another move, the Commerce Department set a quota of 7,000,000 cc. for export of the vaccine in the first three months of 1957. This is the same amount as for the last three months of 1956, and the Commerce Department explained that this high level was being maintained because of the large stocks with the manufacturers.

ANNUITY FOR SELF-EMPLOYED

Weeks in advance of the convening of the 85th Congress, considerable sentiment had been found among the newly elected members for the principle of the Jenkins-Keogh bills. They are the measures that would allow a deferment of taxes on money paid by the self-employed into annuity plans. The American Bar Association's Committee on Retirement Benefits has sounded out House members and found more than half of them in favor of the principle. Of the 435 Republicans and Democrats in the House, 294 were reported in favor, 120 views were unknown, 18 were noncommittal, and only 3 opposed.

Under present plans, a new bill is due to be introduced by Rep. Eugene Keogh (D., N. Y.) that will allow for withdrawal of funds from a retirement plan in advance of age 65 upon payment of a small penalty. The American Medical Association has long supported the Jenkins-Keogh plan because the self-employed are now discriminated against in this field. As early as 1948, the A. M. A. Board of Trustees gave its endorsement of the principle of tax deferment on retirement income.

ARMED FORCES RESIDENCY TRAINING

The Army and Air Force have made separate announcements on their residency training programs. The programs are being given added emphasis in efforts to encourage physicians to enter or remain in the medical services.

The Air Force estimates that since last July 1 a total of 181 of its medical officers have entered residency training in the various medical specialties. Twenty-six are taking training in civilian hospitals, and the rest are assigned to military hospitals. A breakdown of the specialties shows that 33 are taking training in internal medicine; 31 in general surgery; and 20 in obstetrics and gynecology. The Air Force reports that it still has need for more physicians in these specialties and that there are training opportunities also in otolaryngology, pathology, neurology, pediatrics, psychiatry, cardiology, gastroenterology, allergy, and general practice.

The Army is preparing to start its first formal residency training program in preventive medicine next July 1. It will be for a three-year program and is open to Regular Army Medical Corps officers or civilian physicians who accept Regular Army commissions.

Both civilian and military training will be provided over the three years. The first year will consist of an 11-month course in military preventive medicine at the Walter Reed Army Institute of Research, or an equivalent graduate course in preventive medicine or public health at a civilian university.

The second year will be spent in an approved civilian program in a city, county, district, or state health department, and the third year will consist of a formal military residency at a large Army post, with a small portion of the time spent at an Army headquarters under supervision of preventive medicine officers.

Those finishing the full three years will be expected to spend three additional years practicing the specialty to establish eligibility for board examination. For physicians with previous military experience, the military

ARTHRITIS IN THE AGED

L. Maxwell Lockie, M.D.
and
John H. Talbott, M.D., Buffalo

• Because of the many types of arthritis occurring in persons over 60 years of age, therapy must be based on an individual plan suited to that particular person. If the first arthritic attack is severe and in one of the peripheral joints, gouty arthritis should be considered. Here colchicine may be used not only for the initial episode but also in combination with probenecid during the intercritical period. Osteoarthritis, the most common type of arthritis in patients over 60 years of age, may be generally treated with posture exercises, weight control, heat, and aspirin, in addition to individual care. A different form of rheumatoid arthritis may suddenly appear after the age of 60. This condition requires complete bed rest until all activity of the disease ceases. While heat, salicylates, and steroids give relief, gold therapy best seems to stop the progress of the disease. Other forms of arthritic involvement may occur, but, in general, there is a good prognosis for all these conditions.

The challenge of treating the various types of arthritis in patients over 60 years of age is always stimulating. There is so much that can be accomplished that the old saying, "it is your age and nothing can be done about it," does not apply any more. In order to give the greatest relief to the patient, the physician must take time to listen to a detailed history and then to do a careful physical examination. In some instances there are certain laboratory studies and x-rays that are necessary to aid diagnosis and to help in outlining a plan of treatment. Inasmuch as there are different types of arthritis, the correct therapy for each patient must be based on an individual plan suited to that particular person. There are several types of arthritis that are commonly seen after a patient has passed his 60th birthday. These will be discussed under separate headings.

Gout and Gouty Arthritis

If a male has severe acute distress in one of the peripheral joints of the body, the probability that this is gouty arthritis should receive high priority. It is not unusual for the patient to have his first attack when he is past the age of 60. This is one type of disorder of the joints that has significant familial implications. In the majority of patients, it is possible to trace a family history in one or more relatives similarly afflicted. This specific information may be just as helpful in persons in the later decades of life as it is in those in the earlier decades. Approximately 20% of all relatives of gouty patients will have a concentration of uric acid in the serum in the gouty range. However, only a small percentage of these will develop gouty arthritis. An isolated instance of this type of family history is illustrative. In 1940, one of us (J. H. T.) was consulted regarding a 45-year-old man who had had acute attacks of gouty arthritis for more than a decade. His physician noted that this was a case of spontaneous development of gouty arthritis in a member of a family that had no history of the disease. The only living male ancestor was the father, aged 78, who denied any past symptoms suggestive of acute gout. The concentration of uric acid in the serum, however, was in the same range as that of his son, the patient. Three years later, at the age of 81, the father suffered his first attack of gouty arthritis. Two years later, he suffered a second attack.

Significant advances in the understanding of uric acid metabolism have been made during the past decade with the use of isotopes (compounds labeled with radioactive carbon and nitrogen). These investigations have demonstrated the multiplicity of sources of constituents of the uric acid molecule, as well as the many pathways that the various carbon, nitrogen, oxygen, and hydrogen components must travel in order to reach the end-product.

Diagnosis.—The diagnosis of acute gouty arthritis should be presumed upon the clinical evidence and confirmed by laboratory studies. The greatest help in diagnosis, however, is obtained from the clinical characteristics of the acute attack. Sudden onset of acute distress in one of the peripheral joints of the hands or feet of a male points to one diagnosis only. Appearance of the cardinal signs of inflammation—redness, heat, swelling, and pain—in one or more joints of the upper or lower extremities justifies a strong suspicion of gout. The response of acute gout to colchicine, administered orally or intravenously, may be extremely helpful since colchicine is the specific treatment for acute gouty arthritis and has no significant antiarthritic effect in any other type of disease of the joints. Without exception, the other antirheumatic agents that may be given for acute arthritis, such as salicylates, phenylbutazone, and the steroids, are endowed with no diagnostic implications. Relief may follow administration of any of these agents in gouty arthritis as well as in nongouty arthritis. The concentration of uric acid in the serum may also be helpful in diagnosis. Serum or plasma, rather than whole blood, should be used. The patients should have taken no antirheumatic drug within 48 hours of the collection of the blood for the determination of serum urate.

In our clinic, we have found that the patient with gout has a concentration of uric acid in the serum above 6 mg. per 100 cc., irrespective of the stage of the disease and the time in relation to an acute attack. The only agents that modify the concentration are

those that lead to an increased excretion of uric acid by the body, that is, the antigout agents other than colchicine. Colchicine has no demonstrable effect upon uric acid metabolism as determined by either the concentration of uric acid in the serum or the isotope studies.

Treatment.—There are several agents that are now available for the management of an acute attack. Reliance should be placed upon colchicine in the initial episode of gouty arthritis because of its diagnostic as well as therapeutic value. A full course of colchicine therapy should be administered by mouth. Also, one-half the full dose of colchicine may be given during a six-hour period together with 800 mg. of phenylbutazone in divided doses. The adrenal steroids have some antiarthritic properties; however, they probably should be used only for patients unable to take other medicaments and not routinely for management of the acute attack. General measures include rest of the affected joint, a soft diet, and an abundance of fluids.

The management of the intercritical period, which encompasses most of the time for all patients with gout, comprises a few drugs and a few prohibitions—in short, a simple schedule. A high fluid intake is to be stressed, because it aids in the elimination of uric acid from the body. Weight-reduction should be insisted upon, if indicated; a low-fat diet is to be used; and substances high in purine, such as liver, kidney, and sweetbreads, should be avoided. Alcohol, in moderation, and red meat are permitted for most patients. The amount of physical activity should be determined by factors other than the presence of gout. It is believed that there are only two drugs that should be used regularly in the intercritical period. These are colchicine, because of its prophylactic properties, and probenecid, because of its uricosuric action. Patients moderately or severely afflicted with gout should take one or two colchicine tablets every day, while those only mildly afflicted probably should take a few colchicine tablets each week. At either dose level, neither gastrointestinal disturbance nor chronic tolerance to colchicine should develop. We believe that the prophylactic use of colchicine is a significant contribution to the management of this disorder.

Probenecid, the second drug indicated in the management of the intercritical period of gout, is a strong uricosuric agent that produces a 20-30% increase in excretion of uric acid in the urine when administered in doses of 0.5 gm. twice daily. A decrease in the concentration of uric acid in the serum occurs with the increased excretion of this substance in the urine. Probenecid has been used at our clinic for more than six years. During this period of time, the favorable results have predominated and the untoward results have been minimal. The prophylactic action of colchicine complements the uricosuric effect of probenecid. This combination is responsible for the present satisfactory status of the management of this type of disease of the joints.

Osteoarthritis

Most people over the age of 60 have some evidence of osteoarthritis as it is manifested by stiffness, pain on motion, or bony enlargement of various joints. The peripheral joints or the spine may be involved. It is usually annoying, not incapacitating, and is the least serious of all types of arthritis. The symptoms are the result of degeneration of the lining of the joints. Frequently spur formation or new bony growth will occur around the margins of the joints. There is no evidence of infection present. The most common age of patients at onset of symptoms is 45 to 60 years. X-ray findings are often helpful but are secondary to the findings on physical examination. When the hands are involved, the arthritis usually occurs in the interphalangeal joints. There will be some enlargement, which is due to capsular thickening, and no free fluid is present inside the joint cavities. When the terminal joints of the hands are involved, the condition is called Heberden's nodes. The onset of symptoms of these nodes at the end joints of the fingers usually occurs within two years of the beginning of menopause. In 10% of these patients the proximal joints will also become painful and stiff.

Diagnosis.—An important diagnostic sign in osteoarthritis of the hands is the fact that the metacarpal-phalangeal joints are never involved. If ever there is pain or swelling in this group of joints, it is due to rheumatoid arthritis. When the joint between the metacarpal bone of the thumb and the adjacent wrist bone is involved, this is always a manifestation of osteoarthritis. The wrist, elbow, and shoulder may be involved, but the discomfort is diffuse and there is full range of motion present in these joints. The cervical spine is frequently affected. On examination, there is limitation of motion or pain on motion. This may remain localized, or the pain may radiate down the arms and even into the hands. Many patients with osteoarthritis will have a history of whiplash injury due to an automobile accident. The examiner should insist that the patient rotate or tilt the neck to a maximum degree to determine the full extent of disability.

The thoracic spine always shows some spur formation on x-rays, but seldom are any symptoms present. However, the lumbar spine frequently is involved. Lumbago in patients over 60 years of age most often is due to osteoarthritis. The poor posture that most people have assumed while watching television or slouching in easy chairs has aggravated many of these symptoms. Here, x-ray studies frequently show marked spur formation, but it must be remembered that it is a well-accepted fact that many people with extensive bony changes in the spine may not have any symptoms of either pain or discomfort. On examination, there is usually no segmental motion present. Muscle spasm may or may not be found. Most often tests of function of lumbosacral joints show little motion, and, when there is motion, the pain brought about by extending the back may be severe. In patients with disability of lumbosacral joints, the physician may frequently obtain a history of a sit-down fall some time previously.

In cases of arthritis of the hip joints, the patient usually is overweight. Rarely are other joints involved. This form of osteoarthritis progresses slowly and may become very disabling. Of all types of arthritis, it is the most resistant to treatment. In the female who is over 60 years of age and overweight, the knees are likely to be the site of osteoarthritis. There will be some bony enlargement, but no fluid is present in the joint cavity. The center of the pain is over the anteromedial aspect of the head of the tibia. Full range of motion is present. X-ray study frequently shows spur formation at the margins of the bones and also some reduction of the joint space due to cartilage destruction. Occasionally the big toe is involved, but the pain here is never localized at the medial aspect as it is in gouty arthritis.

Although x-ray findings cannot always be correlated with symptoms, in the case of osteoarthritis affecting the knees, the greater the changes seen on x-ray, the greater the patient's complaints.

Treatment.—The treatment of osteoarthritis must be individual for the particular patient. However, a general summary of the steps we use in treatment follows. The patient is taken into our confidence and instructed in detail concerning the diagnosis, treatment, and, as far as possible, what to expect in the future. We recommend that undue strain or excessive use of the involved joints be avoided as much as possible. Inasmuch as most patients with osteoarthritis are overweight, reduction of weight at the rate of 1 lb. per week is advised. This is so important that, if the patient with osteoarthritis of the knees does not lose weight, she is not encouraged to return until there has been some weight loss. The infrared heat of either a simple 250-watt bulb or a metallic element frequently gives considerable help. It should be used two or three times a day for 15 minutes each time, at a distance of approximately 30 in. from the skin, at which distance the heat reaching the patient is not uncomfortable.

Since posture is so important in treatment of osteoarthritis, we suggest that the mattress of the patient's bed should be firm. If a rubber or inner-spring mattress is used, a half-inch piece of plywood should be put under the whole mattress. The patient is encouraged to sit only in straight-backed chairs or in occasional chairs, never in a lounge chair or lounge davenport. To keep the patient mindful of good posture, she is encouraged to stand erect with her shoulders back and take six deep breaths every hour on the hour.

We have found that aspirin is usually the best medicament for the relief of pain or stiffness. The injection of steroids in or around involved joints, particularly the thumb, knees, and big toe, will frequently give excellent results. If there is persistence of pain in the cervical area, the use of traction at home is encouraged. In the case of Heberden's nodes, light massage, two minutes to each finger, after heat treatment, seems to help relieve some of the stiffness. If the lumbar area is involved, a lumbosacral support or even a sacroiliac support relieves the strain.

Rheumatoid Arthritis

Patients may show the results of an old rheumatoid arthritis with marked joint changes, but there also may be another variety of rheumatoid arthritis that is seen frequently after the age of 60. This is by no means unusual. Typically, the patient will have had a sudden onset of rapidly spreading rheumatoid arthritis, previous to which he may have been very well. The proximal interphalangeal joints and the ulnar aspect of the wrist show the greatest changes; there is limitation of extension of the elbows, knees, and ankles. Pain, fatigue, and disability may be great. The laboratory studies show an increase, which may be marked, of the sedimentation rate; anemia is present; and there may be some leukocytosis. The x-ray studies are normal, as the arthritis usually has been present only a short time. Of all patients who have rheumatoid arthritis, these people in the older age group do by far the best.

Treatment.—Complete bed rest without weight-bearing at any time is absolutely necessary for as long as any activity of the disease persists. The bed rest must be supervised carefully in order to prevent deformities in the joints, and the mattress must be firm. The patient is allowed to sit up in bed six times a day for 30 minutes each time. Only one pillow is allowed for the head, and another is put inside the bed at the foot, to prevent the bedclothes from pressing on the feet. At no time is a pillow allowed under the knees. As the patient improves, he is permitted to be up gradually. This period of time naturally increases as the patient continues to feel better.

It is our impression that the intramuscular injection of gold is the most powerful treatment to use to stop the progress of rheumatoid arthritis. Our experience goes back some 22 years, during which time approximately 1,000 patients have been treated. Either of two gold preparations, gold sodium thiomalate (Myochrysine) or aurothioglucose (Solganal), is used intramuscularly. The dosage schedule begins with 10 mg. of the gold salt given intramuscularly the first week, 20 mg. the second week, 30 mg. the third week, and 40 mg. the fourth week. Dosage is then kept at a level of 40 mg. given intramuscularly each week until the patient has had a total of over 500 mg. At that time, it is necessary to decide whether to continue administration at weekly intervals, to reduce the dose, or to increase the interval between doses. The decision will depend entirely upon the condition of the patient. There are some reactions that may occur, but these are familiar to all.

Some form of heat is definitely indicated to help relieve the pain in these patients. An infrared lamp, diathermy unit, or baker is soothing and can be used in the hospital; when the patient is at home, the infrared lamp or baker is helpful. If the hands are involved, paraffin baths are soothing. Salicylates, especially in the form of aspirin, are effective to help relieve pain. The adrenal steroids are used in a few selected patients for a short time only in order to make them more comfortable. At no time are they used unless it is deemed absolutely necessary. Many patients have done very well under this general plan of treatment. In most cases, the prognosis is excellent. It may take months to accomplish this, but time is absolutely necessary in this type of treatment: haste does not help.

Other Conditions

Occasionally diabetes and syphilis produce arthritis that becomes manifest after the patient is 60 years of age. In this type of arthritis there is relatively little pain, but often the instability of the joint is marked. When a patient has severe monarticular arthritis that has not responded to treatment for gout or any other type of arthritis, the diagnosis of a malignant growth must be seriously entertained. This type of arthritis is the only one in which it is necessary to give morphine. The condition of Dupuytren's contracture is frequently overlooked, although the disability produced may be great. Therefore, it is wise to examine the palms of a deformed hand as well as the joints themselves. This disability is not to be confused with osteoarthritis or rheumatoid arthritis.

Comment

It is extremely important to make the correct diagnosis of the type of arthritis that is present. A careful examination is necessary in order to plan a proper program of treatment. Fortunately, a high percentage of patients who have arthritis in the over-60 age group can be benefited markedly, with the aid of correct treatment. The prognosis in general is good.

FRACTURES IN THE AGED

Carter R. Rowe, M.D.
and
Robert C. Detwiler, M.D., Boston

• *Fractures are an important cause of disability and death in people over 70 years old; they are three times as frequent in women as in men, and more than a third of them are fractures of the hip. The coexistence of other causes of disability must be taken into account in planning surgery, but the elderly patient without serious complicating disease is a good operative risk. Sedation, anesthesia, splinting, casts, fixation, and postoperative exercise should be adapted carefully to the individual case, and sometimes they have a profound effect on the attitude and progress of the patient. In cases of compression fractures of the vertebral bodies, no attempt is made at reduction unless dislocation or facet instability has occurred; the compression is accepted, and excellent results are obtained by a suitable program of physical therapy. The fractured hip, a major problem in the aged, is more successfully treated since the introduction of the three-flanged nail for stabilization. It is important to make use of mechanical aids for early ambulation, to relieve pain, restore weight-bearing, and avoid the complication of stiff joints. Continued, organized help after the patient has gone home from the hospital is frequently essential for complete rehabilitation.*

Fractures in the young and fractures in the aged present specific problems. Fractures in children have received wide attention, but the aged have increased in number in recent years and "have come into their own." These patients must now be dealt with as a separate age group with its own special problems.

Recent surveys of patients hospitalized on the fracture service at the Massachusetts General Hospital reveal that aged persons, patients 70, 80, or 90 years old, constituted 25% of admissions. Females outnumbered the males three to one. In this group, fracture of the hip was the commonest fracture (35%), with Colles' fractures second (16%) and fractures of the neck of the humerus third in frequency (14%). There were relatively few fractures of the femur, the tibial shafts, or the ankle. The over-all mortality rate for the aged patients on our fracture service in 1955 was 10%. The mortality rate for those with intertrochanteric fractures was 18% and for those with fractures of the femoral neck 10%. In 57 major operations on elderly persons during the past year, 8% of the "good-risk" and 20% of the "poor-risk" patients died as a result of surgery.

Characteristics of the Aged Patient

Fractures occurring in the elderly person may be complicated by hypertension, some degree of cardiac failure, respiratory complications, malignancy, or metabolic, renal, and nutritional diseases. These may occur at any age, but are found more frequently in the aged patient. Contrary to general opinion, however, the aged patient without serious complicating conditions is found to be a very good operative risk. We agree with Moyer and Keyes [1] that the aged patient should not be denied necessary surgery or specific therapy merely on the basis of "old age," that the "magnitude of the operation is not as important a determinant of operative risk among the aged as is the duration of the period of physiological upset attending it." We have found that the aged patient does not tolerate the added stress of such prolonged complications as cerebral accident, recurrent phlebitis, sepsis, or diabetes.

In one respect the aged are much like children; they need good, constant, intelligent nursing care. In the early phase of treatment for major fractures, they must be made comfortable and turned frequently to prevent pulmonary stasis, pressure sores, urinary stasis, and fecal impaction. Constant pain and immobilization are extremely exhausting to the aged. Restraints and narcotics add to mental confusion and restlessness; when these are eliminated the patient may become more cooperative and quieter. Aspirin in adequate doses and codeine in small doses should control the average discomfort and may be far more effective than strong narcotics. Chlorpromazine in selected cases has proved very effective in relaxing elderly patients and lessening

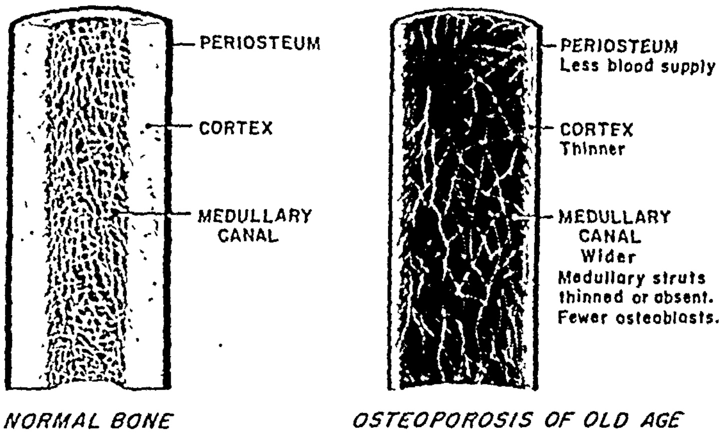
Read in the Symposium on Rehabilitation before the Joint Meeting of the Section on Orthopedic Surgery and the Section on Physical Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

pain. Care, patience, and guidance are needed when the aged patient is taught to walk, because the elderly person may lose his balance easily. Many are discharged to their homes or to a nursing home on crutches, in a plaster cast, or for "bed and chair existence." Much that is gained in the hospital can be lost after discharge by neglect of the patient, mishandling of the extremity, or noncompletion of specific activities and exercises.

Bone Condition.—The bone picture of an aged person reflects his general condition (fig. 1). There are "young," resilient individuals in the 80's whose bone structure may vary little from that of the average adult. On the other hand, there are "old" individuals in the 60's with far-advanced osteoporotic changes. Osteoporotic bone of old age is not "decalcified." In analysis, i. e., grain for grain, the calcium content in osteoporotic bone and normal bone is the same. Rather, there is an actual loss of bone substance or mass. The bone trabeculae are thinner and fewer than normal. The causative factors of osteoporosis in old age are the lack of sex hormones, malnutrition, inactivity, and the aging of tissues.



PERIOSTEUM
CORTEX
MEDULLARY CANAL
PERIOSTEUM Less blood supply
CORTEX Thinner
MEDULLARY CANAL Wider Medullary struts thinned or absent. Fewer osteoblasts.
NORMAL BONE
OSTEOPOROSIS OF OLD AGE

Fig. 1.—Schematic comparison of normal bone and that showing osteorosis that occurs in old age. This condition is caused by lack of sex ormones, malnutrition, inactivity, and aging of tissues.

Due to the loss of bone substance in osteoporosis,[1A] the bone is weaker and more brittle in the aged patient than in a younger individual. The bone heals more slowly, due to the smaller amount of bone equipment—bone substance, osteoblasts, blood clots, and muscle coverage—needed to initiate a good callus. The thin bone cortex and large, poorly filled medullary canal present a definite mechanical problem for early activation and ambulation. Internal fixation, such as plates and screws, is poorly tolerated, so careful evaluation of the patient and the x-ray films is necessary in order to determine whether the bone is strong enough to tolerate internal fixation. Little is gained (in fact, harm may be done) when internal fixation is applied to bone too weak to accept it. In recent years, procedures for intramedullary fixation have been tried in osteoporotic bone. These have been encouraging in selected cases and in experienced hands. Estrogens to stimulate osteoblastic activity, or testosterone to stimulate growth of muscle mass and appetite, and a high-protein diet are useful adjuncts in therapy. Extra calcium itself is not needed; in some instances it may be harmful.

Anesthesia

Careful evaluation of the patient before anesthesia is most important in the aged. We suggest that the preoperative procedures include determination of the patient's hemoglobin level and nonprotein nitrogen level, urinalysis, and taking of an electrocardiogram and chest x-rays. Beecher[2] makes the following suggestions for anesthesia in the aged patient. Relative to major surgery he suggests, "Almost any anesthesia to which the anesthetist is accustomed is good choice for hip fractures in good-risk patients. In poor-risk patients, with anesthetists of varied skill, our patients seem to do best with a combination of nitrous oxide and ether, the ether being used to provide relaxation only when needed." Beecher also says, of preoperative medication, "Minimal doses of sedatives and atropine are wise in pre- and post-operative medication. We like pentobarbital sodium 0.1 gram, intramuscularly with atropine 0.6 mgm. sc."

Reduction of a large number of forearm fractures, particularly Colles' fractures, has been done in our hospital with the use of brachial block anesthesia. This anesthesia allows manipulation of the fracture regardless of when the patient has eaten. There have been 687 brachial blocks performed at the Massachusetts General Hospital, with a 2% incidence of reported pneumothorax. However, Beecher says, "we suspect minor degrees of pneumothorax to occur at a greater incidence." Only one death could be attributed to this complication, so we assume that it is a safe type of anesthesia for aged patients. Against this mortality rate can be balanced that of general anesthesia, a death rate of 1 in 800. Practice in the performance of brachial block is especially important in avoiding complications. Multiple nerve blocks around elbow and ankle joints have been very successful, using a 1% solution of lidocaine (Xylocaine) hydrochloride with epinephrine. The anesthetic effect is prolonged by the addition of epinephrine. Spinal anesthesia is not used in poor-risk patients or in instances of shock or impending shock in the elderly patient.

Fractures of the Upper Extremity

The primary aim in treating fractures of the upper extremity in aged patients is to restore a useful hand, in those of the lower extremity to enable the limbs to bear weight. Fractures of the upper extremity in the aged as a rule heal readily. The disturbing complications are stiff, painful fingers or limited motion in the wrist, elbow, or shoulder. These complications may persist long after the fracture has healed and may become a permanent partial disability.

Colles' Fractures.—In Colles' fractures a gentle reduction is performed with the application of a light, removable "gutter" splint or a plaster cast allowing free motion and use of the fingers. Immediate elevation of the hand after manipulation is very important. If early edema is prevented from occurring, the vicious cycle of edema, pain, and stiffness is eliminated. If the Cotton-Loder position is used, the wrist should be brought to a more neutral functional position as soon as possible. The patient should begin careful elbow motion and shoulder exercises as soon after reduction of the fracture as this can be comfortably performed. Early, clear instruction in this is most important. The same principles apply to fracture of the forearm.

Fractures of Elbow.—In comminuted fractures of the elbow, a light plaster splint is applied with the elbow in a stable position—preferably extended a little beyond a right angle. Finger and shoulder motion should be started early. In displaced fractures of the olecranon, we have had gratifying results by resecting the proximal fragment and suturing the triceps to and over the ulna or distal part of the olecranon. Motion is begun within a week. The functional and cosmetic results have been excellent. This form of treatment eliminates immobilization.

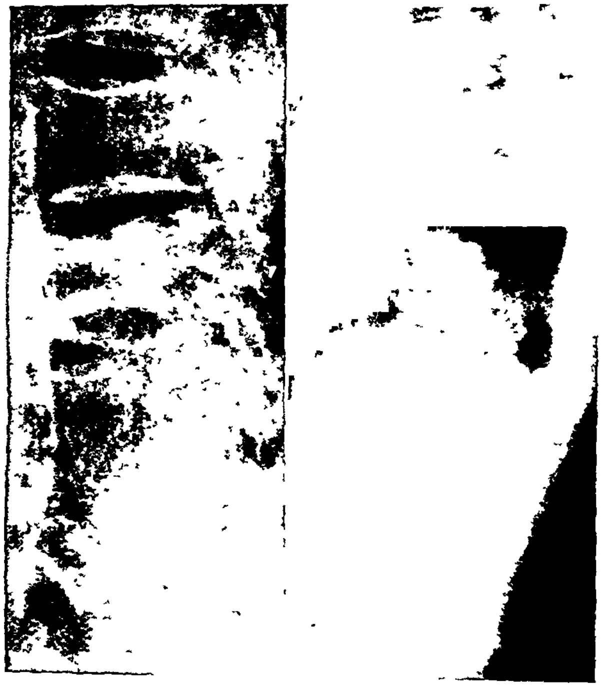


Fig. 2.—Compression fractures of the vertebral bodies in aged patients with osteoporosis. *Left*, roentgenogram of a 79-year-old man who suffered a compression fracture of the first lumbar vertebra from a fall. *Right*, roentgenogram of an 85-year-old woman, showing compression of the fourth lumbar body.

Fractures of Humerus and Shoulder.—In fractures of the humerus, we favor conservative closed methods of treatment with light-weight coaptation splints with the arm at the side or a light-weight hanging cast. In fractures of the shoulder, the patient is made comfortable with a sling and swathe, an axillary pad, and the arm at the side. An anatomic reduction is not a prerequisite to good function, and, as a rule, repeated manipulation or open reduction is not necessary. Shoulder motion is started early, the swathe is removed as soon as possible, and normal activities of the arm are begun within the limits of comfort.

Fractures of Spine.—The aged patient with a "broken back" is a very different problem from the young adult or middle-aged patient with this condition. Elderly patients, particularly females, may develop rather severe osteoporosis, especially in the vertebral bodies. This is commonly referred to as postmenopausal osteoporosis. Compression fractures of the vertebral bodies may be produced from slight strain or merely a jolt (fig. 2). As a rule, no attempt is made to reduce the vertebral fracture in the elderly patient unless dislocation or facet instability has occurred. The compression is accepted, the patient is allowed to assume comfortable positions in bed, and hot packs and mild analgesics are used. The patient is encouraged to walk as soon as the pain subsides, which is usually within a two-week to three-week period. The clinical results with this program have been excellent. When reduction is attempted, the fracture usually returns to its original deformity when the patient becomes ambulant. Attempted reduction of fractures of vertebral bodies in the aged may also invite serious complications.

Following is an outline of suggested treatment: Plaster casts are rarely used, and hyperextension is not used to reduce the fracture. We advise bed rest, with hot packs applied four times a day for 20 minutes until pain has subsided, and administration of enteric-coated aspirin (0.6 gm.) four times a day. A high-protein diet is recommended, in addition to therapy with testosterone or estrogen in selected cases. Muscle-setting exercises should begin early, as should ambulation, with the patient wearing a well-fitted corset.

Fractures of the Lower Extremity

The fractured hip is the major problem in the aged patient. Bigelow,[1] in 1869, wrote, "The prognosis of these fractures is difficult to give. Elderly people may die of them at the end of a few weeks, or may linger many months." Much has been accomplished since that time. When Smith-Petersen, Cave, and Van Gorder[4] reported their results using the three-flanged nail to stabilize fractures of the hip in 1931, the management of fractures of the femoral neck was put on a safe and reasonable basis. Stabilizing the fracture

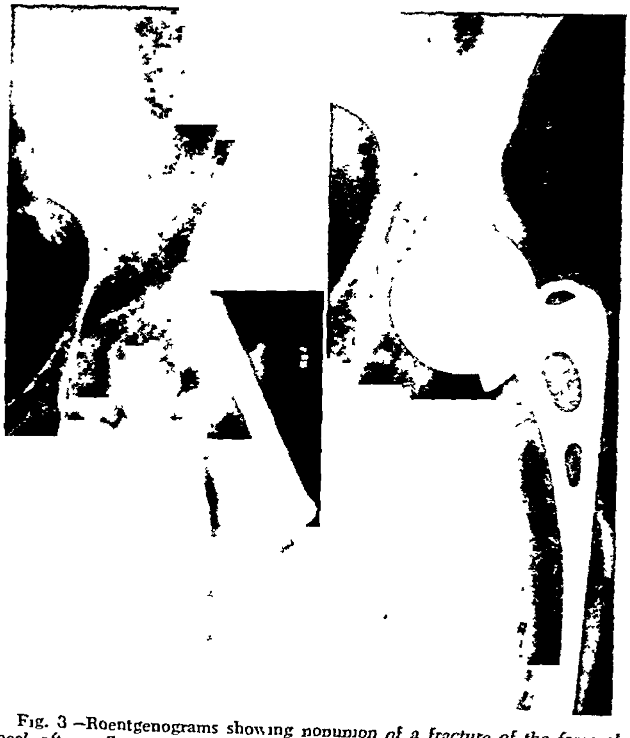

Fig. 3—Roentgenograms showing nonunion of a fracture of the femoral neck after nailing in a 75-year-old woman. *Left*, nonunion of neck of left femur. *Right*, insertion of a Moore-type Vitallium prosthesis.

relieved pain and allowed the patient to be turned and to be made ambulant within a reasonable length of time.

Since then, many types of appliances have been used to stabilize fractures of the femoral neck. In recent years, replacement prostheses of various types have been used in fresh fractures of the femoral neck that could not be satisfactorily reduced or in the very old patient who would have to be made ambulant within a few days of surgery. The technique of introducing the prosthesis in the aged person must be adapted to osteoporotic bone. When the replacement prosthesis is used in selected cases and by experienced surgeons, the results have been very good. In inexperienced hands, some very distressing complications have occurred.

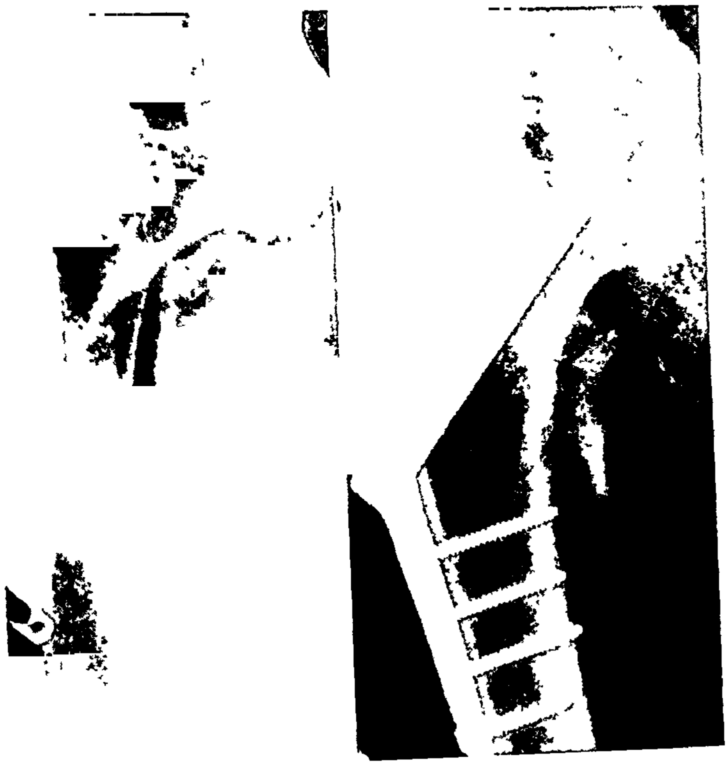

Fig. 4.—Roentgenograms showing an intertrochanteric fracture suitable for internal fixation in a 75-year-old woman. *Left*, intertrochanteric fracture with little comminution and strong fragments. *Right*, internal fixation with a Jewett nail-plate combination.

There is general agreement today that nonunion of the neck of the femur occurs in approximately 20 to 25% of fresh fractures of the femoral neck that have been nailed. Aseptic necrosis develops in 60% of those with nonunion of the femoral neck.[3] The replacement prosthesis has been a definite help in allowing the patient to recover from these complications and to become active in a relatively short time (fig. 3). Other reconstructive operations, such as the geometric osteotomy of Dickson, the Colonna procedure, or shaft arthroplasty, using a Vitallium mold, can be very successfully employed. Impacted fractures of the neck of the femur in valgus position, with good anteroposterior and lateral roentgenograms, are stable in a high percentage of cases and may be treated satisfactorily without operation. Some surgeons prefer to nail or introduce a screw for fixation in these fractures.

Intertrochanteric fractures occur in an older age group than fractures of the femoral neck. Stable fractures can be treated without operation, but six to eight weeks are necessary before ambulation is safe. The decision for open reduction and internal fixation with a nail-plate combination depends upon the quality of the bone and the degree of comminution Badly comminuted fractures with marked osteoporosis may respond poorly to open reduction; in fact, harm may be done by introducing some form of internal fixation. The fragments are too brittle to be held by nail and plate combinations. However, when the quality of the bone is good and the fractured fragments are strong, a nail-plate combination will prove very effective (fig. 4).

Fractures of Femoral Shaft.—Fractures of the femoral shaft in the aged are serious. Some patients are physically able to tolerate traction and suspension, whereas others become mentally confused by enforced immobilization and confinement to bed. This reaction seems more severe in patients with fractures of the femoral shaft than in those with fractures of the hip In a large percentage of patients, the bone structure of the femur is too osteoporotic to tolerate "onlay fixation," such as plate and screws.

Intramedullary fixation of fractures of the femoral shaft in the aged patient has been a distinct advance. There are many technical problems, such as the thin cortex of the femoral shaft and large medullary space. We have used the largest Küntscher nail (11 or 12 mm.) or a "nesting" of nails (2/12-mm. nails) to obtain good internal fixation. Parham bands around comminuted fracture fragments aid greatly in stabilizing the fracture site. An intramedullary rod will eliminate pain and allow motion and nourishment of the patient.

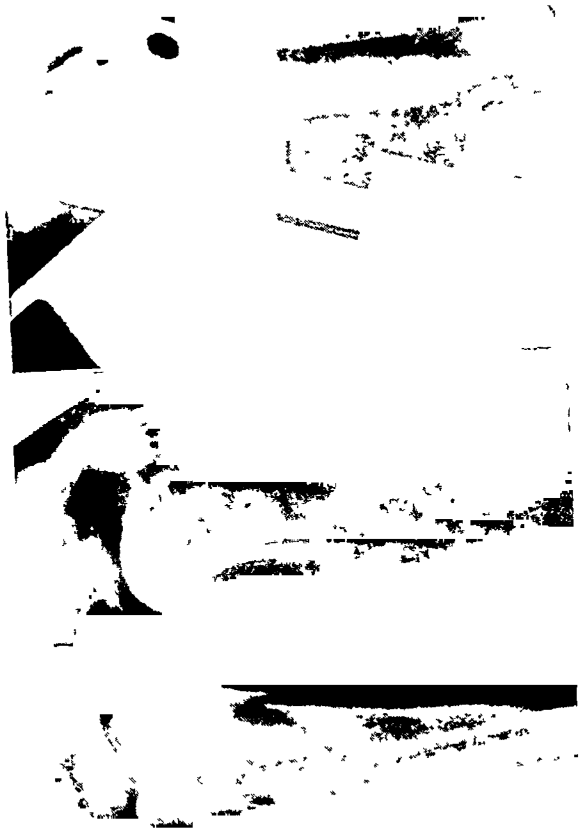

Fig. 5.—Treatment of a 73-year-old woman with a comminuted fracture of the femoral shaft above the condyle on a Bohler frame, with traction through the tibial tubercle. Roentgenograms showing, *top*, traction and suspension with a wire through the tibial tubercle, *center*, consolidation of the fracture at the time of ambulation, and *bottom*, consolidation 10 weeks after injury.

Many patients can be in a chair or walker in a relatively short time. A confused elderly patient whose condition is deteriorating changes within a few days to a clear-minded, cooperative, happy individual. A word of warning is necessary. Intramedullary fixation calls for experienced surgeons, proper instruments, and adequate help. Unless these are available, this form of surgery should not be attempted.

Fractures of the Femoral Condyle.—Elderly patients tolerate fractures of the femoral condyle much better than they do fractures of the femoral shaft or even those of the femoral neck. It is surprising how well they do after treatment with a pin or Kirschner wire through the tibial tubercle, with balanced traction and early motion of the knee (fig. 5). Open reduction, using a Blount nail or plate, is indicated in some instances. However, the bone must be strong enough to tolerate the stabilizing equipment. In figure 6, a poor selection of a case for internal fixation is shown. Although good reduction was obtained, the bone was too porous to retain the apparatus.

Pathological Fractures

The possibility of metastatic disease should be considered in any elderly patient with fracture of a long bone, particularly a fracture of the humerus or femoral shaft. A chest roentgenogram should be taken routinely, and a skeletal survey completed if necessary.

Intramedullary fixation is frequently indicated in pathological fractures, expecially in those involving the lower extremities. Pain is relieved, and the patient may walk and return home in comfort within a relatively short time. Death usually intervenes before the local area is affected to any extent by tumor growth.

In fractures of the femur due to osteitis deformans (Paget's disease), intramedullary fixation has proved very effective for early ambulation of the patient. It has been necessary to perform an osteotomy on the shaft above or below the fracture site, in order to introduce the rod. The patients actually appreciate having their legs straightened, and several have stated that they were waiting to break their other femur "in order to have two straight legs"! Figure 7 illustrates the remodeling and change in stress lines following introduction of a Küntscher rod for a fracture of the femoral shaft due to osteitis deformans.

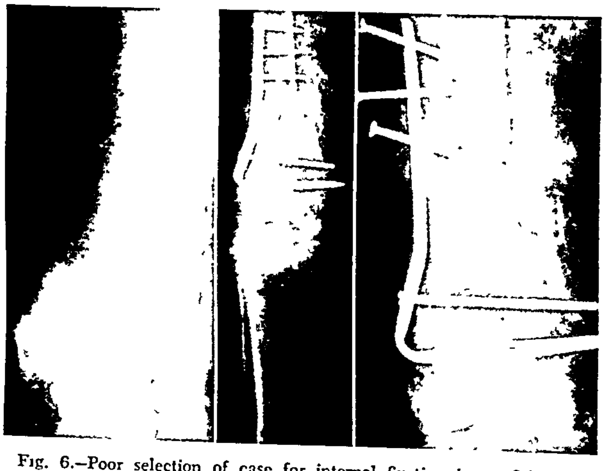

Fig. 6.—Poor selection of case for internal fixation in an 85-year-old woman. Roentgenograms showing, *left*, a displaced supracondylar fracture of the femur, *center*, good reduction with a Blount plate and screws, and, *right*, plate and screws not held by weak osteoporotic bone.

Need for Long-Term Care

Much progress has been made in the treatment of fractures in aged patients during their period of hospitalization. This has come about through the combined efforts of the surgeon, physician, nursing service, anesthesia service, and physical therapy department. Social service has been of inestimable service in individual cases but is limited in the over-all picture. Organized efforts in the care of the aged patient fall off abruptly, however, when the patient is discharged from the hospital. The average mother taking care of her home and her children is not able to give the necessary time and care to a grandmother recovering from a broken hip. The average nursing home lacks the trained personnel and equipment for adequate care and rehabilitation of the aged patient. There is an urgent need at the present time for organized long-term care and supervision of the injured aged patient during the period of recovery after hospitalization. This help should come from local, state, and federal governments and should be patterned after the state crippled children's program. The problem of the injured aged patient is with us at the present time. There is every indication that it will continue to grow.

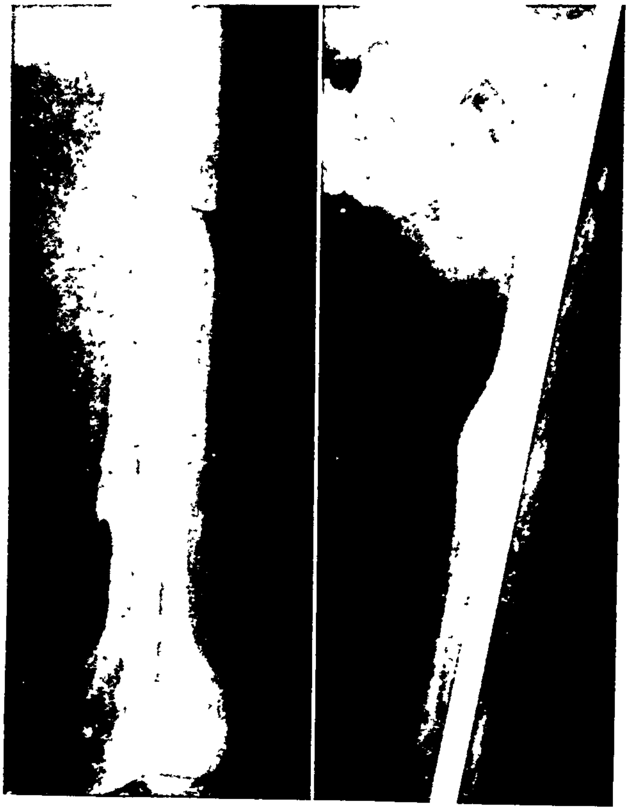

Fig. 7.—Roentgenograms showing intramedullary nail (11 mm. in diameter) used for stabilization of a femoral fracture in an 84-year-old man with osteitis deformans (Paget's disease). *Left*, fracture through the lower third of the femur. It was necessary to perform osteotomy on the femur above the fracture in order to introduce the straight nail. *Right*, improvement in cortex one year later after intramedullary fixation.

Summary

With the increase in longevity, and better care of the hospitalized patient, aged persons in the population have become a gradually enlarging group with specific problems of their own. One of these problems is the unique treatment of fractures necessary in this age group. As a rule, fractures of the upper extremity in the aged patient can be treated with good results, as these do not confine the elderly patient to bed; the primary concern is to avoid the complications of painful, stiff joints. In fractures of the lower extremity, mechanical aids frequently must be used in order to permit early ambulation. The primary aim is to relieve pain and restore weight-bearing. Specific attention must be given to the general condition of the patient and the degree of osteoporosis present.

Much progress has been made in care of aged patients during their hospital stay. However, comparatively little progress has been made in their care during the period of recovery after hospitalization. There is an urgent need for organized help to the aged patients after their discharge from the hospital.

MENTAL REACTION TO TRAUMA AND HOSPITALIZATION IN THE AGED

Edward M. Litin, M.D., Rochester, Minn.

• *The removal of an elderly person to a hospital during acute illness or after an injury involves certain difficulties and dangers that need to be recognized. Disorientation leads sometimes to delirium, which in severe cases can exhaust the patient. Many simple steps can be taken to aid the patient in keeping oriented, such as having a member of the family at hand, leaving a night light on, and avoiding sedatives that may increase the patient's confusion. The presence of familiar objects and the observance of familiar rituals such as a nightly drink of brandy have excellent sedative effects. Early ambulation and occupational therapy are important. If such measures fail and delirium becomes dangerously severe, the patient should be transferred to a psychiatric ward or hospital for special care.*

The behavior of elderly people frequently, and perhaps unfairly, is compared to that of children. However, many parallel patterns do exist in the sphere of emotional reactions to trauma and hospitalization. The child reacts in an apprehensive, confused, and sometimes terrified manner to an injury and sudden transfer from a familiar environment to strange hospital surroundings. The organization of his personality is as yet insufficient to integrate these changes, and the consequent anxiety is frequently overwhelming. These reactions are intensified during the night, when the semidarkness and shadowy figures give full rein to the child's fantasies and imagination. It is often amazing how a child's anxiety can be ameliorated by the presence of a familiar person or a familiar toy from home. These serve as ties between the child and home, thus diluting the separation and ensuing strangeness.

Many of the same reactions are seen in aged persons after trauma and hospitalization. The single most constant symptom in elderly persons under such circumstances is that of delirium, which, as in the child, is greatly intensified at night. The delirium is characterized by complete disorientation for time, place, and person; some degree of agitation and panic frequently is apparent, and, in the more severe forms, destructiveness and incontinence appear. Depending on various individual factors, the patient may exhibit hallucinations, paranoid delusions, or combativeness and literally may exhaust himself. The delirium often may be far more dangerous than the original trauma for which the patient was hospitalized. Again, as with the child, relatively simple measures, such as the presence of a familiar person or illumination from a night light, may prevent the appearance of delirium. Such measures allow the elderly patient to orient himself and remain oriented, which is so difficult in the face of an impaired memory for recent events.

Cause of Disturbed Behavior

Many observers have assumed that this disturbed behavior in old age is purely the result of organic pathological-anatomic brain changes. This automatically implies that the disturbance is irreversible, which in turn leads to a fatalistic approach that is not justifiable in view of the excellent results sometimes obtained by thorough and vigorous treatment.[1] Autopsy findings have shown that many older persons who have never had disturbed behavior and who were quite clear mentally have far-advanced senile and arteriosclerotic cerebral changes. Conversely, many of those who have exhibited disturbed and confused behavior have little, if any, cerebral damage.[2]

The question remains as to what does account for the disturbed behavior so often seen in older persons, particularly after trauma and hospitalization. In large measure, the answer is to be found in the premorbid personality and in the youth of the person in ques-

tion, namely, the psychological deficits and conflicts that he carries with him into the increasing pressures of advancing age. Part of the aging process is diminution of resiliency and flexibility and a lessening capacity to adapt to change or stress. The more deficient, immature, or neurotic are the psychological adaptations of earlier years, the smaller is the stress required in old age to produce disorganized or disturbed behavior. Thus, minimal cortical damage is catastrophic to one person and relatively unnoticed in another.[3] Elasticity of the cerebral arteries, although extremely important, is not the only factor; equally significant is elasticity of the personality, as characterized by the ability to adjust to earlier stresses.

Hospitalization

It is obvious that in many cases there is no choice regarding hospitalization of an aged person after trauma. Surgical and orthopedic procedures often must be carried out, and these can be done only in the hospital. In these instances, it is well to be aware of some general principles that may be helpful in warding off serious senile delirium. I shall refer to these principles later. However, in many instances hospitalization has actually been quite harmful and perhaps was the cause of death. This is indeed paradoxical, in that hospitals have as their main and perhaps sole function the relief of suffering and prolongation of life. Report of an illustrative case may be appropriate.

A 79-year-old man had been retired from active business for 11 years and was in remarkably good health. He lived alone with his wife in a small home in which they had resided for the previous 23 years. The patient was fairly alert, except for some forgetfulness and a slight decline in the quality of his personal habits. In January, 1954, while doing some woodworking around the home, he struck his head on a beam. It is not known whether he lost consciousness, but his wife noted that he was somewhat incoherent in his speech. A small hematoma was noted in the right temporal area of the scalp. He was brought to the hospital emergency room, where a careful neurological examination was done and roentgenograms of the head were obtained. Results of the examination were negative, except for mild disorientation and mild impairment of recent memory. It was considered that the patient should be observed in the hospital for 24 hours.

He was slightly restless and mildly confused that evening, but he soon fell asleep after a bedtime dose of 1½ grains (0.1 gm.) of a fast-acting barbiturate. After he had been asleep for about two hours, the nurse heard him calling loudly. When she entered the room, she noted he had a very frightened expression and was calling for his wife and for his son, who had been killed in World War II. He was completely disoriented in all spheres, confused, agitated, and obviously frightened. He was negativistic and refused any medication, thinking that it was poison. It was necessary literally to carry him back to bed and restrain his arms and legs. He was given two hypodermic injections of barbiturates, which appeared to increase his restlessness. He called out all night and struggled against his restraints.

The next morning he appeared ill. He was dehydrated, incontinent of urine, and exhausted. Neurological findings of a focal nature were absent. The psychiatric consultant considered that the patient's condition was not directly related to the head trauma but most likely was a nocturnal delirium aggravated by barbiturates. The patient's wife and daughter stayed with him that day, they fed him and reassured him repeatedly concerning his condition and hospitalization. He was given fluids and vitamins intravenously, and at bedtime he was given his usual brandy. His daughter sat up in his room during the night, and a light was left on. Sedation was not given, and he slept well. When he awakened during the night, his daughter would speak to him and he would quickly drift off to sleep again.

The following morning, the patient was back to normal. He was oriented, calm, and cooperative. The only residual effect was amnesia for the night before and the feeling he had experienced a nightmare. He was dismissed after a neurological recheck examination gave negative results.

Fortunately, this case had a happy ending. The main injury suffered by this patient was not from the blow on his head but from his hospitalization. A period of observation was definitely indicated in this case, but the question remains as to where such observation should be carried out. The answer would appear to be the home, if this is at all possible. Admittedly, this plan is far from ideal in many cases, but the benefits derived from the avoidance of delirium or a state of confusion far outweigh the disadvantages of such an arrangement. In some instances, such delirium and ensuing exhaustion have progressed to the point where electroshock therapy becomes necessary literally as a lifesaving device. In studies regarding nocturnal delirium in the aged, Cameron[4] found that darkness of the room, combined with impairment of recent memory, results in disorientation. Because of loss of retentive powers, the patient is unable to maintain a spatial image without repeated visualization. This disorientation leads to misinterpretation of the environment and lays the foundation for full-blown delirium.

Thus, a primary decision to be made by the physician is the desirability of hospitalization of elderly persons. It is to be remembered that the trauma itself is a serious stress on the elderly patient's ability to make the necessary adjustments. Physical trauma also becomes a mental trauma when the elderly patient foresees a period of helplessness and further dependency, loss of self-esteem, and financial burden. It is easy to see how trauma, with all its physical, emotional, and social implications, can precipitate profound neurotic or psychotic reactions in an elderly person whose capacities are already seriously taxed by the mere act of existing in a society geared to a large extent to the needs of the young and healthy. To add the necessity for the further adjustment to a strange hospital routine is sometimes asking too much.

Although delirium is the most common mental reaction to trauma and hospitalization in the aged, it is by no means the only one. Depressive reactions, either agitated or retarded, are frequent. Also, acceleration of a mild senile dementia may occur or a caricature of a preexisting neurotic reaction may be presented.

Prophylactic Measures

A number of measures can be helpful in avoiding mental complications after trauma in the aged when there is no alternative to hospitalization. Relatives should be asked regarding any special habits or rituals the patient may have; these should be continued providing they do not interfere seriously with hospital routine. For example, an elderly woman who was accustomed to having two glasses of hot lemonade every morning was greatly relieved when she was assured this routine could continue in the hospital. Patient, careful, simple explanations regarding his injury or illness and hospitalization are also helpful to the aged person. The physician must remember that the attention span and recent memory of such patients are often impaired and that repetition is essential.

The prodromal symptoms of an impending delirium or a state of confusion must be watched for. It is relatively easy to recognize such signs, which include restlessness and irritability, easy mental fatigability, mild confusion and disorientation, and increased loss of recent memory. If a surgical procedure is contemplated, it should be postponed when these prodromal symptoms appear. A member of the family should be enlisted to stay with the patient, and a light should be left on at night. With the appearance of restlessness, there is a tendency to prescribe sedatives and narcotics. Many geriatricians unyieldingly forbid the use of barbiturates and bromides in the aged patient. There is a tendency toward excitement or depression of vital functions because of the cumulative effect of these drugs. A good general rule is to give as few doses and as small amounts of medication as possible. Whisky or brandy in eggnog is an excellent nightly sedative in some instances. Brandy has been called the "milk of the aged," and the danger of alcoholism at this period is negligible.[5] Judicious use of the newer tranquilizing drugs, especially chlorpromazine, has been extremely successful in eliminating the need for sedatives and reducing agitation and anxiety.

Ambulation as early as possible is beneficial not only for medical reasons but also for the mental improvement to be derived from the patient's being less restricted in activities and being able to make more social contacts. Such adjuncts as occupational therapy should be employed.

Unfortunately, despite following of the best medical and psychiatric principles, delirium may occur in a significant number of elderly patients. If the delirium is severe, with danger of exhaustion and even death, the patient should be transferred to a psychiatric ward or hospital.

Summary

As patients grow older, the stress of physical trauma and hospitalization may often precipitate a serious mental disorder when the capacities for adjustment are already overtaxed. These psychiatric complications may be far more dangerous than the original reason for hospitalization. If at all possible, observation and treatment of the aged should be carried out at home and hospitalization should be avoided. The commonest and most dangerous psychiatric complication is senile delirium. Although this complication cannot always be avoided, some relatively simple measures and avoidance of overmedication can greatly reduce the frequency of its occurrence.

PHYSICAL MEASURES IN THE AGED

Donald L. Rose, M.D., Edward B. Shires, M.D.
and
William S. Alyea, M.D., Kansas City, Kan.

• *Two physical aspects of disability in the aged have been especially studied, namely, the inefficiency of respiration and the inadequacy of ambulation. Habitual underventilation of the lungs was suspected in some patients because their vital capacity increased so promptly and so greatly after a program of breathing exercises and because this was accompanied by so marked an improvement of general condition and attitude. Similar evidence led to the conviction that the early achievement of ambulation in the elderly patient is more important than the concentrated exercising of particular groups of weakened muscles.*

The various techniques of physical medicine and rehabilitation in the treatment of specific clinical syndromes in the elderly patient have been well documented.[1] The purposes of this paper are to call attention to the disturbances in bodily functions produced by acute and chronic hypoxia, to demonstrate the need for including in the rehabilitation program measures to improve the efficiency of external respiration when disturbances exist, and to emphasize the necessity for early attempts at ambulation.

Certain changes in bodily function have traditionally been associated with the "normal" process of aging.[2] Among these are pupillary changes, with miosis and sluggish reflex responses to light and distance; changes in ocular movements, with progressive restriction in the movements of convergence and defects in upward gaze; generalized muscular wasting; tremors on effort; elevation of the thresholds for perception of the stimuli of light touch, vibration, and pain; other reflex changes, with loss of superficial reflexes and diminution or loss of the ankle jerk; impairment of the drive to accomplish normal activities; and diminution in strength together with sharp limitations of endurance.

From the Department of Physical Medicine, University of Kansas Medical Center.

Read in the Symposium on Rehabilitation before the Joint Meeting of the Section on Orthopedic Surgery and the Section on Physical Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

Perhaps because much of society functions by means of machines of one type or other, we have tended to regard our own bodies as machines. The aging process in various body tissues has been compared to the wearing out of component parts of the machine. That this concept is incorrect may be demonstrated in a number of ways. Changes have been described in neural tissue in the aged that are interpreted not as degenerative processes but as processes of an essentially defensive nature that place the cell in a better position to withstand the metabolic vicissitudes of old age.[3] Work with isotopes has revealed an unexpectedly rapid turnover of protoplasmic constituents in neural tissue at all ages.[4] For these reasons the neuron should be regarded not as a stable system but rather as a system in which there is a steady flow of productive activities. However, there may be degenerative changes within the nervous system that lead to decreased functional abilities and eventually to the death and disappearance of many cells. The difficulty apparently is in the correlation of the functional with the organic changes. Since there is agreement that the changes that modify function precede the final organic changes in the course of the so-called aging process, any therapeutic program might well include consideration of those factors that modify function, in addition to the more easily demonstrable organic factors.

Hypoxia

Whatever else the elderly patient may complain of, fatigue and lack of endurance are extremely common. It has been pointed out that the capacity for work and the fatigue induced by it are related to the intensity and duration of the work.[5] At the one extreme is a 50-yd. dash, which may last five seconds; at the other extreme is a day's labor in heavy industry, which may last as long as 12 hours. In the first example, the work is accomplished by the scanty reserves of oxygen in the body together with the body's resources of anaerobic energy. In the second, the work performed is chiefly on an aerobic basis. Obviously, most daily activities fall into the latter category. The body tissues vary considerably in their susceptibility to hypoxia.[6] The frontal lobes of the brain, for example, are more readily damaged by hypoxia than the rest of the brain cortex or other parts of the central nervous system. The small pyramidal cells of the cortex are more sensitive than the cellular components of the medulla or the spinal cord. The myocardium is the tissue next most sensitive to oxygen deficiency. The permeability of the pulmonary capillaries, and therefore gaseous exchange in the lungs and the function of the adrenal glands, is also influenced by hypoxia. On the basis of these observations, hypoxia certainly can be considered among those changes that may modify function. It remains to demonstrate that a basis for hypoxia exists in the problems encountered in the physical rehabilitation of the aged.

It has long been known that the vital capacity is approximately 10% less with the patient in the supine position than in the erect position and that there is a reduction in vital capacity with age.[7] There seem to be few studies dealing with the magnitude of changes in vital capacity in the older person and more specifically in the elderly patient who has a physical infirmity that we frequently attempt to modify with rehabilitation procedures.

Although clinically one can see a lag in the hemithoracic movements in the patient with hemiplegia, the shallow upper chest respiration in the individual with pulmonary emphysema, and gross disturbances in pulmonary mechanics in other conditions, it is easy to measure vital capacity with acceptable accuracy and thus provide objectivity for such impressions. While vital capacity is not a valid criterion for the degree of efficiency of pulmonary function under all conditions, such measurements do provide a means for observing the progress of a patient over a period of time as well as for comparison of the patient's capacity with normal values.

We have employed the Bennett respiration ventilation meter[8] not only to check the vital capacity of the elderly patient but also to determine the minute volume of respiration for normal quiet breathing. The percentage of the predicted normal attained by the patient with respiratory difficulties may be determined by comparison of the findings for that patient with standard vital capacity tables. The resting minute volume, rather than maximal breathing capacity, was selected because this figure was considered to be a more satisfactory reference base for the respiratory demands of functional activities.

The results of these studies to date indicate that normal vital capacity and minute volume values occur very seldom in the ill older person. None of the patients tested had a vital capacity of more than 70% of the predicted normal; the majority had capacities below 50% of normal. The resting minute volume was reduced in many patients but usually approached normal values. From these findings, it would seem that patients tested were breathing very nearly at their maximal respiratory ability. If this were true, additional functional demands could be met only if there were a proportionate improvement in respiratory efficiency. In fact, unless such improvement in respiratory function could be achieved, the added functional demands of rehabilitation efforts might well contribute additional acute hypoxia to any chronic hypoxia already present.

Improvement of Respiratory Function

Our efforts to improve efficiency of respiratory function have included use of specific breathing exercises and two mechanical devices. It is usually fairly easy to determine whether there is a relative insufficiency of inspiratory or expiratory efforts, whether atony or spasticity of the abdominal musculature interferes with the normal reciprocal relationship between the abdominal and diaphragmatic musculature, or whether there is a disproportionate movement of the two halves of the thorax. The breathing exercises we recommend[9] are directed toward maximal excursion of the rib cage and improvement in diaphragmatic function. These have been deliberately simplified as much as possible in order that they may be incorporated more easily into the daily activities of the elderly patient.

Intermittent positive-pressure breathing[10] is clinically valuable, especially in treating those patients in whom there is pulmonary emphysema and those who, through chronic illness or prolonged bed rest, have developed atony of the thoracic and abdominal musculature and loss of elastic recoil of the rib cage during expiration. The intermittent positive-pressure device consists basically of a flow-sensitive cycling valve with mouthpiece, gauges, and regulators for the introduction of oxygen in concentrations up to 100% and aerosol solutions containing bronchodilator drugs when these are indicated.

There are many patients who, for a variety of reasons, are unable to eliminate accumulated bronchial secretions satisfactorily.[11] An exsufflator (Cofflator) is effective in meeting this type of pulmonary ventilation need. By means of this device, the lungs are inflated fully with a positive pressure of 30 to 40 mm. Hg followed by a swift reversal to negative pressure of 20 to 40 mm. Hg. This procedure will produce an expiratory volume flow rate several times greater than that produced by a maximal cough and is effective in removing retained bronchial secretions.

Three to five such "coughs" administered once daily, intermittent positive-pressure breathing before and after exercise, and attempts to carry out breathing exercises repeatedly throughout the day have resulted in nearly every case in increased exercise tolerance, less fatigue after exercise, and an improvement in general physical capabilities. An increase of approximately 1,000 cc. in vital capacity has occurred in those patients with the greatest diminution from normal, although all patients increased their vital capacity. Occasionally the increase was so rapid as to cause one to suspect disuse as a cause for diminished respiratory function similar to the diminution noted in other neuromuscular functions. In addition, rather unexpected improvements in patients' attitudes often followed treatment. Patients showed improved outlooks on their physical condition, spontaneous cheerfulness, greater emotional stability, increased attention spans, and increased drives to help themselves.

Early Ambulation

Coupled with efforts to improve respiratory function have been attempts to help the patient achieve ambulation as rapidly as possible. The production of, not necessarily the maintenance of, ambulation activities has been stressed. We believe that the longer the delay in instituting these activities, the greater the difficulty in achieving them. Accordingly, very early use is made of the standing table, so that the proprioceptive-motor patterns of movement can be initiated and exercise of the torso and upper extremity musculature, balance exercises, and breathing exercises can be carried out fairly efficiently with complete lack of fear of falling on the part of the patient. As soon as possible, forward, backward, and side-to-side walking in the parallel bars or with assistance is carried out, with simple, lightweight splinting of a weakened lower extremity when indicated. We have regarded the early achievement of ambulation by the elderly patient as more important than concentrated effort on reeducational exercises for separate areas of weakened muscles.

Summary

Those elderly patients with ailments requiring physical rehabilitation exhibit reduction in efficiency of pulmonary function so frequently that the effects of hypoxia must be included among the etiological factors entering into the disability. Specific retraining efforts for proper breathing coupled with mechanical efforts to increase pulmonary air flow improve the efficiency of external respiration. The increase in exercise tolerance and improvement in certain psychic functions following such treatment would suggest improvement in internal respiration as well. Attempts to stand and to walk at the earliest practicable time, aided by graded exercise procedures, also materially shorten the rehabilitation period.

The assistance of a clinical training fellowship for Dr. Alyea by the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare is acknowledged.

Coccidioidomycosis.—A correlation between the periodic dust storms occurring in the endemic area and the incidence of new cases of coccidioidomycosis has been noted. These dust storms enable the resistant spores to be transported far from their natural habitat. Cases have been recorded wherein the disease undoubtedly was contracted by the patient merely passing through the endemic area. . . . The majority of those infected with Coccidioides immitis may remain asymptomatic and present no stigmas of active disease. . . . The chest roentgenographic findings, while not specific, often will be the first clue to the diagnosis and will suggest that the physician obtain confirmatory laboratory studies. A rarer, malignant, secondary or disseminated form of this disease occurs approximately once in every 400 cases among the white race, and approximately ten times as frequently in the darker skinned races. This disseminated or granulomatous form of the disease has a mortality of more than 50 per cent.—Capt. W. A. Peck Jr. and Major S. S. Romendick, M.C., U. S. Army, Coccidioidomycosis: A Roentgen Study, *Texas State Journal of Medicine*, February, 1956.

FATALITIES FOLLOWING TOPICAL APPLICATION OF LOCAL ANESTHETICS TO MUCOUS MEMBRANES

John Adriani, M.D.
and
Donovan Campbell, M.D., New Orleans

• *The hazards of local anesthesia are due to the rapid absorption of the drug into the vascular system. The etiology of the reactions may be due to a disregard of the amount of anesthetic applied, the use of a topical anesthetic for the first time, or the fact that resuscitative equipment or antidotes were not immediately available. Concerning tetracaine, reactions may be abrupt, with no prodromal signs or convulsions. The dose of tetracaine that may be infiltrated should not exceed 100 mg., therefore the dose for topical application must be considerably less.*

It is surprising that many physicians are unaware of the hazards of local anesthesia. The pioneers in this field recognized and emphasized the pitfalls that result from the misuse of local anesthetic drugs. In 1919, Eggleston and Hatcher[1] studied the toxic effects of procaine, cocaine, and other local anesthetics and indicated that untoward reactions were largely due to the rapid absorption of the drug into the vascular system. Other investigators have since then reiterated this fact. Thus, the potential dangers of these drugs have been known for some time. Those who consistently use local anesthetics are familiar with their hazards. The occasional users are less versed in the subject and usually encounter the majority of difficulties.

Accurate statistics on the frequency of untoward reactions and fatalities due to local anesthetics are not available, because few such mishaps are reported. We are familiar with 10 unreported fatalities in a 15-year period in this institution caused by the topical application of tetracaine to mucous surfaces for endoscopic procedures. In addition, we are aware of five unreported fatalities occurring under similar circumstances outside the institution but in the approximate geographical area. Besides being consulted for the fatalities, we and our associates have been called upon to assist in the treatment and management of numerous other nonfatal reactions. In scanning the protocols of fatalities, one is impressed by the relative frequency with which these have occurred following topical application of local anesthetic drugs. The problem of reactions following the use of local anesthetics, both topically and otherwise, at one time was of such concern, that, in 1924, a commission was delegated by the American Medical Association[2] to review the status of the available drugs and make recommendations concerning dosage and technique of usage. The situation has improved steadily since their report was formulated, but preventable deaths from this cause are still all too frequent.

Characteristics of Tetracaine Reactions

In a review the protocols of fatalities due to tetracaine, the following findings are consistent: 1. The operator had little regard for dosage, was unaware of the maximal allowable quantity, and was unable to indicate the exact amount used. In cases in which the quantity used was known, in most instances it exceeded 8 ml. of a 2% solution (160 mg.). 2. The individual using the drug was a novice learning to do endoscopic procedures. He had used the drug occasionally or was using it for the first time. 3. The reaction was abrupt in onset, without prodromal manifestations. Syncope and circulatory collapse were the usual manifestations. Convulsions did not occur. 4. The drug was used in situations in which resuscitative equipment and antidotes were not immediately available. 5. Barbiturates were used as antagonists in some instances, even though the patient was in respiratory failure and there was no indication for their use.

It is the intent of this report to emphasize the extreme potency and relative frequency of toxic effects from tetracaine and not to incriminate the drug as a lethal substance that should be discarded. Untoward reactions have occurred following the application of other topical anesthetics such as piperocaine, cocaine, and lidocaine. The train of symptoms heralding the untoward response with these, however, has been different. Central nervous system stimulation, characterized by excitement, apprehension, and convulsions, has been the usual manifestation. The intravenous injection of barbiturates counteracted these reactions.

The major distinction between reactions due to tetracaine and those of the other aforementioned drugs has been the absence of convulsions and the abrupt onset of syncope. The interval between the onset of symptoms and the moment of the fatal termination was brief. The train of events occurred so quickly, and in such rapid succession, that there was little time for evaluation of symptoms, differential diagnosis, and antidotal therapy. It must not be construed, however, that convulsions are not manifestations of systemic reactions to tetracaine. They can and do occur with this drug and have occurred in our experience. Convulsions followed the topical application of tetracaine in two instances. These reactions were successfully antagonized by thiopental, and both patients survived.

Cocaine is at the present time the anesthetic of choice for topical use in this institution. Reactions occur from time to time, but none has terminated fatally, even though the total number of reactions and

Read before the Section on Anesthesiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

total number of usages far exceed those for tetracaine. Excitement and convulsions have been the usual manifestations of cocaine intoxication.

Postmortem examinations in the aforementioned catastrophes revealed little to suggest the mechanism causing death. For the want of a better explanation, the cause of death was recorded as due to sensitivity to the drug, anaphylactic reaction, allergy, and so on. There was little evidence to substantiate these diagnoses.

The incidence of reactions with use of tetracaine by other routes has been considerably less than with the topical route. Moore,[3] Bonica,[4] and others have described the use of tetracaine for nerve blocking without untoward reactions or fatalities in cases numbering into the thousands. Tetracaine is one of the most widely used drugs for spinal anesthesia. Fatalities due to intoxication following intrathecal injection are unknown. In our experience at the Charity Hospital over a 15-year period, spinal anesthesia has been induced with tetracaine about 20,000 times without a single untoward response suggestive of a toxic reaction. Others have used tetracaine for spinal anesthesia and have had similar experiences. This is probably due to the fact that local anesthetics disappear slowly from the intrathecal space and the over-all dosage is comparatively minute (15 mg. or less). When fatalities have occurred from spinal anesthesia they have been due to severe, uncontrollable hypotension due to the autonomic blockade or from respiratory failure caused by paralysis of the intercostal muscles and the diaphragm due to the ascent of the drug into the thoracic and cervical segments of the cord. Certain clinicians[5] have infused tetracaine slowly, intravenously, without apparent untoward results.

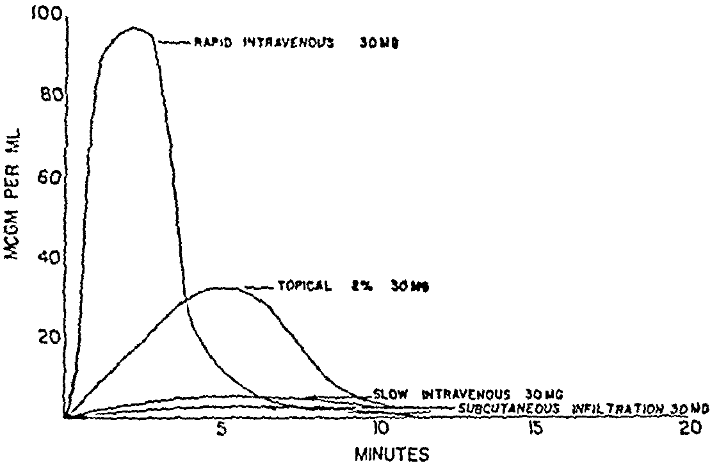

Fig. 1.—Comparison blood levels obtained after injecting 30 mg. of tetracaine in dogs intravenously and rapidly over a 30-to-60-second interval, after application topically to the pharyngeal mucous membranes, after subcutaneous infiltration, and after slow intravenous infusion.

Frequency of Tetracaine Reactions

All of this prompts several questions. "Why are systemic reactions more frequent after topical application?" "Why was sudden syncope the most common manifestation?" It has been suggested that local anesthetics topically applied undergo a change as they pass through the mucous membrane and become "more toxic." We feel this is highly improbable. The symptoms of intoxication following topical application differ in no way from those of reactions due to direct and rapid intravenous infusion of the drug.

Conflicting statements appear in the medical literature concerning absorption of local anesthetic drugs from mucous membranes. Almost everyone assumes that they are rapidly absorbed, but blood level studies to substantiate this assumption are not available. Eggleston and Hatcher[1] indicated the role of rapid absorption in causing reactions but did not determine blood levels. Seevers and his co-workers,[6] studying the metabolism of cocaine, injected the drug subcutaneously, intravenously, and into the stomach but did not study absorption from the pharynx, trachea, bronchi, or other mucous surfaces.

We felt that blood level studies would provide a clue to the cause of high reaction rate and have undertaken this study. For obvious reasons the study was done in the laboratory on dogs. Blood levels were determined after the absorption of tetracaine from mucous surfaces of the pharynx, trachea, and bronchi. These were compared with those obtained after rapid intravenous injection, subcutaneous infiltration, and slow intravenous infusion of tetracaine (fig. 1). The rapid injection of 6 mg. per kilogram of body weight of tetracaine intravenously resulted in peak levels of 100 mcg. or more per milliliter in the circulating blood within one to two minutes. The same quantity applied to the mucous membranes of both pyriform fossae of the pharynx or instilled into the trachea resulted in peak levels of 30 mcg. per milliliter. The peak was attained within four to six minutes. The peak was not as high, nor did it rise as abruptly, as that noted after rapid intravenous injection, but it obviously simulated it closely. There was little difference between the curves obtained after the pharyngeal and tracheal instillations. Epinephrine, 1:7,500, added to the tetracaine solution did not retard absorption. The blood levels were nearly identical to those obtained without epinephrine.

In one set of experiments the total dose was doubled, divided into three fractions, and applied at equal intervals over an 8-to-10-minute period. The blood level gradually attained a peak of 20 mcg. per milliliter after 10 minutes. Thus, it is obvious that the gradual application of a solution results, as one would expect, in a gradual rise in blood level. It is important to note that identical blood levels were obtained when the total dosage in milligrams remained constant but the concentration was varied from 2 to 4%. Thus, the blood level is a function of total dosage and not of concentration (fig. 2). The blood level was not detectable when 6 mg. per kilogram was infiltrated subcutaneously in an area 3 by 4 cm. over the abdomen. The slow intravenous infusion of 6 mg. per kilogram over a 20-minute period likewise caused no detectable quantity in the blood after the injection was complete.

The free base was precipitated and applied to the mucous membranes. The blood level curves were identical to those obtained when solutions of the hydrochloride were used. The absorption of the hydrochloride incorporated in a water-soluble cream applied to mucous surfaces is prompt and rapid and occurs with ease. These data indicate what has not been realized, namely, that the topical application of a given dose results in blood levels that closely simulate those obtained after rapid intravenous injection.

The epithelial surfaces of the pharynx, trachea, and the posterior urethra provide excellent absorbing surfaces. Drugs are readily absorbed from the pulmonary alveoli because the osmotic pressure relationships in the pulmonary vascular bed are designed to prevent collection of fluid in the alveolar spaces. Volunteers inhaling free nebulized cocaine (4%) immediately experienced the stimulation characteristic of this drug and felt no appreciable numbness in the upper respiratory passages.

Circulatory Effects

Most physicians are generally aware of the effects of these drugs on the central nervous system; they are less familiar with the circulatory effects. Local anesthetics depress cardiac tissues.[7] The myocardium may be so depressed that asystole results. This depressant effect of local anesthetics has been utilized to prophylactically decrease cardiac irritability and thus obviate arrhythmias during thoracic surgery. Eggleston and Hatcher[1] demonstrated that digitalis administered prior to the infusion of toxic doses of local anesthetics protects animals from cardiac failure. Local anesthetics also cause vasodilatation. Extreme hypotension occurs when myocardial depression and vasodilatation occur simultaneously. There is no reason to assume that both the circulatory and nervous systems cannot be involved simultaneously, particularly when overwhelming doses are used. In fact, the evidence in some of the protocols suggests that this is exactly what happens. Circulatory and respiratory failure occurred simultaneously. The circulatory effects of tetracaine are exemplified by the following case report.

Report of a Case

A 67-year-old white woman was admitted to the hospital for diagnostic bronchoscopy for a possible carcinoma of the lung. She was given premedication of morphine, 1/6 grain (10 mg.), and scopolamine, 1/100 grain (0.6 mg.), one hour prior to the time of her arrival in the operating room. The nasopharynx was sprayed with a 2% solution of tetracaine. An estimated 5 ml. was then instilled into the trachea with a curved cannula. The operator made no note of the total dose used. Several minutes after application of the anesthetic, the patient uttered a sharp cry and slumped over from the upright position. An ashen gray cyanosis appeared over her face and neck. She became comatose. She was placed in a supine position. The pulse was thready and barely palpable. The blood pressure was unobtainable. The neck veins were engorged. Respiration was shallow and rapid. Administration of ephedrine, 15 mg., caused a feeble fleeting pressor response, after which the blood pressure disappeared. Additional doses were ineffective. Pulmonary edema then developed. Oxygen under positive pressure was administered by mask. Attempted digitalization with ouabain was futile, and death ensued one and a half hours after injection of the drug. There was no evidence of preexisting cardiac disease. The train of symptoms developed within three to four minutes after the instillation of the drug. The bronchoscopy had not commenced; hence, the cause of death was ascribed to cardiac failure.

Of the drugs possessing topical action, dibucaine and tetracaine are the most potent and most toxic. Procaine, the least toxic local anesthetic in current use, is devoid of topical action. Most endoscopists concede that tetracaine is the most serviceable drug from the standpoint of effective topical anesthesia. The term "potency" applied to topical anesthetics is not easily defined. Tetracaine, for example, when directly applied to a nerve trunk, is 10 times more potent than procaine. In other words, 1 mg. causes a blockade when 10 of procaine are necessary to obtain the same effect. However, potency is difficult to dissociate from duration of action. Tetracaine, in addition to being more potent on a weight-for-weight basis, causes a blockade that lasts approximately twice as long as that of procaine. With the exception of dibucaine, which few clinicians use, it is the longest lasting of the available topical anesthetics.

Evaluation of Topical Action

The topical effects of local anesthetics are not easily evaluated. In the laboratory, topical action is usually studied by applying a fixed quantity of a drug to the cornea of experimental animals and noting the duration of absence of the corneal reflex. Such studies merely suggest trends as far as the value of a drug for clinical use is concerned. In clinical evaluation of these drugs, the variables encountered are too numerous to make a study clear-cut and simple. The types, sizes, and arrangement of cells composing the mucous surfaces, the blood supply, the nature of the submucous tissue, and the type of neuroreceptors present introduce a multitude of variables. Some of the pain felt during instrumentation of mucous surfaces undoubtedly arises in the submucous areas where the drugs do not necessarily penetrate in sufficient concentration to cause effective blockade. A possible answer to the existing impression that tetracaine appears to be superior to other topical anesthetics may be that it anesthetizes these deeper structures more effectively and for a longer period of time.

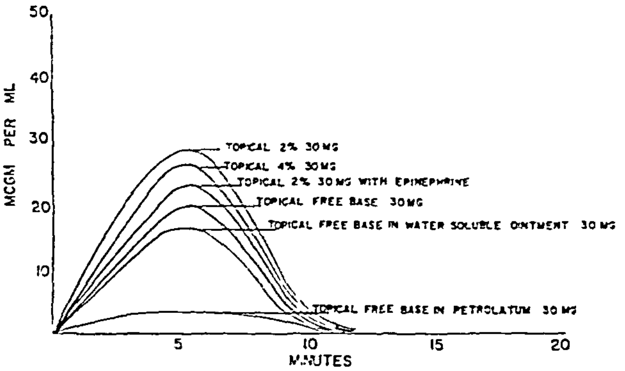

Fig. 2.—Comparison of blood levels of tetracaine in dogs after application to the mucous membranes of tetracaine hydrochloride. 30 mg. of the free base, 30 mg. in 2 and 4% solution with and without epinephrine, 30 mg. in a water soluble base, and 30 mg. in a non-water-miscible base.

In our studies conducted in 23 volunteers, it was observed that the order of duration and degree of numbness experienced for topical anesthestics applied to the mucous surfaces of the palate, lip, site of the tongue, and the fauces is as follows: tetracaine, cocaine, lidocaine, piperocaine, hexylcaine, benzocaine, tripelennamine (Pyribenzamine), and pramoxine (Tronothane). A latent period precedes the onset of local anesthesia whether the agent is topically applied or injected. The longest period preceded tetracaine; the shortest, benzocaine. Since the degree of numbness was used to indicate potency of the topical effect of the drug and since this is a subjective manifestation, one is justified in challenging these results. We, however, know of no other effective way of studying the clinical usefulness of these substances.

Water solubility of a drug and its ability to diffuse through membranes play important roles in topical anesthesia. Benzocaine, for example, is poorly soluble in water (0.5 gm. per liter). When applied to a mucous surface, it is absorbed more slowly than cocaine, tetracaine, and other drugs. Untoward reactions due to systemic toxic effects are virtually unknown from use of this substance. An ointment containing 20% benzocaine (Americaine) has been used in this department nearly 10,000 times as a lubricant for intratracheal catheters and for pharyngeal and nasal airways to obtund the pharyngeal and tracheal reflexes without any untoward effects.

Dosages

It is impossible to state the lethal doses of the different anesthetics for man because such doses vary with the route of administration, rate of absorption and elimination, and tolerance of the individual to the drugs. Values are often quoted that are based upon lethal doses in animals or on impressions derived from clinical experience. Such data merely indicate trends and are useful as guides but are not absolute values.

Thus, it cannot be emphasized too strongly that when a drug is applied topically a maximum total dosage must be decided upon that must not be exceeded at any one sitting. Tetracaine is considered to be 10 times more toxic than procaine. On the basis that 1 gm. of procaine is the maximum quantity recommended for infiltration, it follows that 100 mg. of tetracaine must not be exceeded for infiltration. Furthermore, when topical application is used, allowance must be made for the greater ease of absorption from the mucous membranes. The total quantity, therefore, should be considerably less than that used for infiltration. Carabelli[8] has obtained adequate anesthesia with a 0.25% solution of tetracaine. He suggests a maximum limit of 20 mg. applied in fractional doses. Rubin and Kully[9] suggest 50 mg. as the upper limit. This must be applied in fractions over a period of 15 to 20 minutes. Wiesel and Tella,[10] using quantities not exceeding 40 mg. for 1,000 endoscopic procedures, noted 19 reactions. Seven of these were convulsive. The remainder were classified as "mild circulatory." There were no fatalities. It is obvious, then, that quantities of 180 to 200 mg., which were associated with death, were excessive.

Treatment of Reactions

In the event a serious reaction occurs, one is faced with the problem of respiratory failure and asystole. If cardiac arrest is suspected, immediate opening of the thorax and cardiac massage is indicated. If the heart has not stopped but the blood pressure is unobtainable, vasopressors such as ephedrine, methamphetamine (Desoxyephedrine), or methoxamine or other similar drugs should be administered intravenously. Artificial respiration must be instituted immediately and maintained throughout the period of apnea. Obviously one should not undertake the topical administration of local anesthetics where it is not possible to immediately institute resuscitative measures.

Summary and Conclusions

Fatalities and untoward reactions occur more frequently when local anesthetics are used topically than when they are administered by other routes. Rapid absorption has been presumed as the cause, but data in support of this contention have not been available. Studies of blood levels of tetracaine indicate that this occurs and at a more rapid rate than has been supposed. A quantity of drug that results in no detectable blood level when infiltrated subcutaneously gives levels when applied topically that are equal to one-third to one-half of those after intravenous injection. The untoward responses are due to the rapid passage of the drug from the site of application into the systemic circulation. The absorption from mucous membrane is far more rapid than clinicians have realized and simulates intravenous administration. Study of the fatalities that have occurred indicates that the cause of death is overdosage from rapid absorption.

Shock.—The clinical syndrome of shock is well known to all physicians, but for purposes of this discussion, shock is considered to be present when, in a previously normotensive patient, the systolic pressure is 80 mm. Hg or below, accompanied by the signs of circulatory collapse such as cyanosis; cold, clammy, moist skin; rapid, thready pulse; and narrowed pulse pressure. In patients with pre-existing hypertension, the clinical syndrome of shock may be present when the systolic pressure is 100 mm. Hg or even higher, depending on the degree of hypertension existing previously.—F. N. Talmers, M.D., T. J. Regan, M.D., and H. K. EVALUATION OF CORTISONE IN THE TREATMENT OF CEREBRAL INFARCTION

Mark Dyken, M.D.
and
Philip T. White, M.D., Indianapolis

• *Thirty-six patients brought to a hospital with symptoms of cerebral infarction were classified as to the severity of the condition and divided into two groups comparable as to severity, age, blood pressure, and other essential criteria. Both groups received the usual supportive care. The test group of 17 patients received, in addition, 300 mg. of cortisone and 3 gm. of potassium chloride daily with a low-salt diet. The cortisone was given in divided doses, and the dosage was reduced after the second day. The contra-test group of 19 patients received a placebo. There were 13 deaths in the cortisone and 10 in the placebo group. The difference, though small enough to have arisen by chance, discouraged further use of cortisone in this situation. The classification according to severity was found to have prognostic value, and an impressive number of patients were seen who could not be admitted to either group because their symptoms cleared up spontaneously within a few hours. Cortisone must not be used indiscriminately. Its unfavorable effects in this series of patients occurred despite observance of known contraindications. Emphasis in cases of cerebral infarction should be on general supportive treatment.*

The high incidence of cerebral vascular disease in the United States confronts physicians with a vital problem. In addition to being the third highest cause of death in this country, cerebral vascular disease is attended by a high degree of morbidity. In 1952, it was estimated that 170,000 persons died from this type of disease. At that same time it was estimated that there were 1,800,000 survivors from previous years, each with residuals of varying degree. Of those who died, 44,000 were in the productive age group 25-65.[1] The scope of this problem indicates the need for intensified, adequate research pertaining to the causes and treatment of this type of disease.

In spite of much research, no truly effective means of treating cerebral vascular disease has yet been discovered. Many of the articles refer to supportive care as being the only treatment available; certainly in cerebral hemorrhage the mortality figures attest to the inadequacy of this form of treatment.[2] With cerebral infarction, however, there is more hope and there are interesting theoretical possibilities for treatment. Cerebral infarction can occur secondary to an embolus or thrombus, but in over 60% of the brains showing infarction no embolus or thrombus could be found.[1] This observation has given rise to several stimulating theories as to the cause of the infarctions. Among the proposed causes has been arterial spasm,[3] producing changes in blood flow and blood pressure, relative ischemia, and tissue destruction.[4] Even in infarction due to emboli or thrombi, dissolution and fragmentation of the emboli and thrombi could occur as part of the general process.

Regardless of the mechanism at the onset, it is probable that there first occurs an area of necrosis in the area completely dependent on the occluded vessel and, surrounding this, an area of tissue reaction characterized by ischemia and edema. This secondary area gradually becomes necrotic, with development of further tissue reaction; in this manner the infarction may theoretically propagate itself. If the blood flow to this ischemic area could be increased or the surrounding tissue reaction decreased, ultimate recovery of the area might be possible. There would be more prompt recovery and fewer residuals. In addition, the mortality would be lowered by shortening the critical phase associated with the secondary infections that frequently follow bed rest in older patients.

Attempts at therapy have been multiple. Use of bilateral stellate ganglion blocks has been both widely supported and condemned.[5] Its value has not been supported by results in an adequately controlled series of cases. Several agents, such as papaverine, carbon dioxide, and procaine hydrochloride,[6] raised false hopes, which were shattered when their use was evaluated in larger controlled series. At the present time, preventive therapy with anticoagulants appears to be of some value in specific types of cerebral vascular disease; at least the anticoagulant drugs promise to prevent the development of new symptoms and signs.[7]

In a recent report, cortisone was described as remarkably decreasing morbidity, mortality, and the estimated ultimate deficit in acute cerebral infarction.[8] Because of the potential dangers and complications associated with the use of cortisone, it was thought desirable to attempt a further evaluation of this drug under controlled conditions.

Method of Study

In general, the method used was to admit all patients to the neurological service as soon as possible after the onset of symptoms. At that time they were placed in groups according to the severity of the disease, the degree of severity being determined by various factors (table 1). The index to severity was established by previous personal observations and other observations in the literature.[5f] After being assigned to severity groups, the patients were alternately treated within each severity group either with cortisone or with placebo. In addition, at all times during this series one of us (P. T. W.) checked on the evaluation of the severity of the patient's condition and on the ultimate progress of the case, without having knowledge at any time as to the drug the patient was receiving. The steps followed in evaluation and treatment are discussed in more detail below.

CLINICAL NOTES

SEVERE CITRATE INTOXICATION DURING CARDIOVASCULAR SURGERY

Theodore F. Hubbard, M.D.
Delbert D. Neis, M.D.
and
John L. Barmore, M.D., Omaha

Over the past years a number of authors have called attention to the potential dangers of a decrease in the ionized calcium level in blood of recipients of large volumes of citrated blood. Citrate intoxication has become a common problem during replacement of a large volume of blood in exchange transfusions, in the more aggressive management of various types of hemorrhage, and during cardiovascular surgery. A progressive fall of the ionized calcium level in the blood may cause tetany, prolongation of the Q-T interval and S-T segment of the electrocardiogram, prolongation of mechanical ventricular systole, hypotension unresponsive to further infusions of citrated blood, and finally cardiac arrest. Citrate intoxication may rarely be responsible for some impairment of the coagulation mechanism.[1]

The clinical warning signs of muscle tremors and tetany are usually absent in patients in deep shock or in surgical anesthesia, and, since there is no readily available laboratory procedure for the determination of the ionized calcium level of blood, the electrocardiogram usually provides the most useful indication of the development of citrate intoxication. In the case reported, rather extreme electrocardiographic and hemodynamic changes developed due to citrate intoxication in a patient with the tetralogy of Fallot undergoing an infundibular resection. Since during such procedures we routinely monitor the electrocardiogram and record right ventricular and pulmonary artery pressures, a fortuitous delay in obtaining calcium for administration allowed observations on these and other physiological variables during development and restitution of advanced citrate intoxication.

Report of a Case

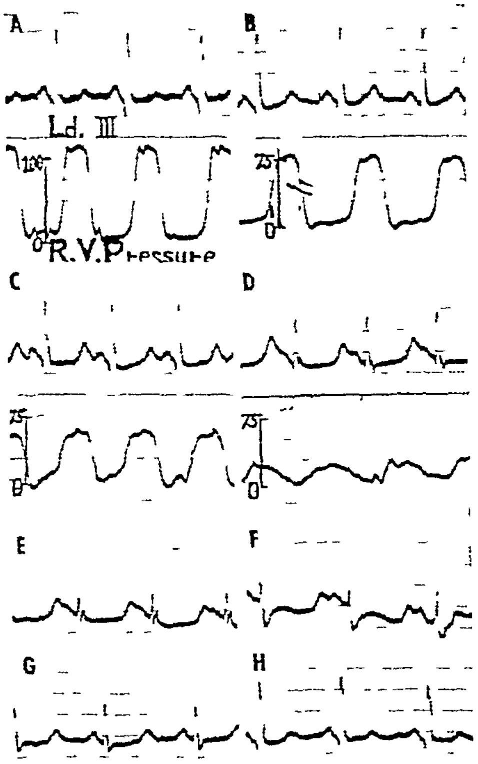
A 24-year-old woman had been moderately cyanotic since birth. In recent years there had been progression of cyanosis and increasing dyspnea on exertion. Cardiac catheterization and other studies confirmed the clinical diagnosis of tetralogy of Fallot. The resting arterial oxygen saturation was 62% and the hemoglobin level equal to 22 gm. per 100 cc.

On April 3, 1956, an infundibular resection was carried out through a purse-string incision in the anterior portion of the right ventricle. At the start of the procedure the systemic blood pressure was 98/65 mm. Hg; the right ventricular pressure, 110/5 mm. Hg; the duration of right ventricular systole, 0.36 sec.; and the corrected Q-T interval of the electrocardiogram ($Q\text{-}T_c = Q\text{-}T/\sqrt{R\text{-}R}$), 0.46 sec. (see figure, *A*). Blood was infused under pressure according to the estimated amount of blood lost at cardiotomy, and over the course of the first 15 minutes of the infundibular resection the blood losses amounted to about 500 cc. (see figure, *B*). Over the next few minutes an additional 250 cc. of blood was administered and definite prolongation of $Q\text{-}T_c$ became apparent but was disregarded because of the small amount of blood that had been transfused to that point (see figure, *C*). With continued administration of blood, definite evidence of citrate intoxication became apparent with further prolongation of $Q\text{-}T_c$, a fall in right ventricular systolic pressure, and a drop in systemic arterial pressure to 50 mm. Hg systolic. Technical delay in administering the calcium allowed further observations of electrocardiographic changes as the infusion of blood was continued. Notwithstanding an increased rate of infusion of blood, the systemic arterial pressure became unobtainable and there was further prolongation of $Q\text{-}T_c$, with development of broadening and change in the contour of QRS and depression of the S-T segment (see figure, *E* and *F*). The duration of right ventricular systole was increased from 0.36 sec. at the start of the procedure to 0.49 sec. just prior to the administration of calcium. There was a period of cardiac arrest lasting for four or five cycles, with resumption of contractions after three or four cycles of massage. At this point, 4 cc. of a 10% solution of calcium chloride was injected directly into the cavity of the right ventricle; within three minutes the systemic pressure had risen to 80/60 mm. Hg and $Q\text{-}T_c$ had shortened from 0.71 sec. to 0.54 sec. (see figure, *G*). An additional 5 cc. of 10% calcium chloride solution was given intravenously, and within 10 minutes the systemic blood pressure had risen to 110/85 mm. Hg and the electrocardiogram had returned essentially to the configuration obtained at the initia-

---

From the Bishop Clarkson Memorial Hospital and the College of Medicine, University of Nebraska.

tion of the procedure (see figure, *H*). Approximately 1,500 cc. of citrated blood was administered from the start of the procedure until the time the calcium chloride was administered; the last 1,000 cc. was infused over approximately 15 minutes (each unit of blood consisting of 440 cc. of donor blood and 110 cc. of anticoagulant acid-citrate-dextrose solution B). The patient's postoperative course was uncomplicated.



Electrocardiographic studies of 24-year-old woman *A*, lead 3 of electrocardiogram and right ventricular pressure wave at start of infundibular resection Q-T_c = 0.46 sec, systemic arterial pressure = 98/65 mm Hg, right ventricular pressure = 110/5 mm Hg, and duration of right ventricular systole = 0 36 sec. *B*, 15 minutes after start of resection, 500 cc. *of* citrated blood had been administered Q-T_c = 0.5 sec., systemic pressure = 90/60 mm. Hg, right ventricular pressure = 80/5 mm Hg, and duration of right ventricular systole = 0 42 sec *C*, *after an additional* 250 cc. of citrated blood, Q-T_c = 0 6 sec., systemic pressure = 85/60 mm. Hg, right ventricular pressure = 60/5 mm. Hg, and duration of right ventricular systole = 0 42 sec *D*, after an additional 350 cc *of citrated blood,* Q-T_c = 0.66 sec., systemic systolic pressure = 50 mm Hg, right ventricular pressure = 20/0 mm Hg, and the duration of right ventricular systole = 0.49 sec *E*, after an additional 200 cc. of citrated blood, Q-T_c = 0.67 sec., there is notching of QRS and depression of the S-T segment The systemic blood pressure was unobtainable. *F*, after another 200 cc. of citrated blood, Q-T_c = 0.71 sec, a broad S wave has developed, QRS has been prolonged to 0.1 sec, and there is further depression of S-T. *G*, 3 minutes after intracardiac injection of 400 mg. of calcium chloride, Q-T_c = 0 54 sec *H*, 15 minutes after intravenous injection of an additional 500 mg of calcium chloride intravenously, Q-T_c = 0.47 sec and electrocardiogram shows little difference from *A*.

Comment

Recent clinical and laboratory studies have indicated renewed interest in the problem of citrate intoxication and awareness of its increasing incidence. Bunker and associates [1] have recently presented clinical studies of several aspects of citrate intoxication. Furman and associates [2] and Gustafson [3] have presented studies of the electrocardiogram during exchange transfusions in erythroblastotic infants. Cookson and associates [4] have indicated the hazards of citrated blood during cardiac surgery and hypothermia. In the case herein reported approximately one-third of the patient's blood volume was replaced by citrated blood in a period of about 30 minutes. The electrocardiographic changes in this case were more marked than have usually been reported. They included a progressive increase in Q-T_c from 0.46 sec to 0.71 sec. There was depression of the S-T segment, with some increase in the amplitude of the T waves. At the height of the changes there was delay in interventricular conduction with change in the form of the QRS complexes. There was a progressive fall in the systemic arterial pressure and the systolic pressure in the right ventricle that was unresponsive to further infusion of citrated blood. Just prior to the calcium injection the heart began to dilate, the rate slowed, and there was sinus arrest for several cycles. With dilatation of the heart, there was further drop in the systolic pressure in the right ventricle and prolongation of mechanical systole. but, in spite of the feeble contractions, the end diastolic pressure in the right ventricle did not rise. All these changes were completely reversed within a few minutes after the injection of rather small amounts of calcium chloride.

Summary

Rather extreme cardiovascular changes occurred due to citrate intoxication in a young woman with the tetralogy of Fallot undergoing an infundibular resection. All changes were promptly reversed by the administration of small amounts of calcium chloride.

Atherosclerosis.—The lipoproteins in the bloodstream constitute an entire spectrum of molecules, varying in size and density from the giant chylomicra—in which form alimentary neutral fat is carried in the thoracic duct—down to the smallest high-density particles. Gofman and his coworkers believe that the sequence of lipoprotein molecules represents a chain in which *metabolic* interconversions are going on in the blood. The largest particles are composed predominantly of neutral fat, and this component diminishes with decrease in particle size. Following the injection of heparin, lipemia clearing can be demonstrated and ultracentrifugal analysis reveals a decrease in the larger low-*density lipoproteins*. The total amount of circulating fat is reduced. Since heparin is normally present in the bloodstream, and the lipemia clearing process has been demonstrated in human plasma without prior injection of heparin, this mechanism is probably physiologic. It is involved in the transport and disposal of absorbed alimentary neutral fat. Failure or deficiency of the process might well be of fundamental significance in the accumulation of excessive quantities of low-*density* or beta lipoproteins in the circulating blood. Thus a heparin deficiency has been suggested by various workers as a possible etiologic factor in serum lipid metabolic defects.—H. Engelberg, M.D., The Prophylactic Management of Coronary Atherosclerosis, *Geriatrics*, June, 1956.

COUNCIL ON PHARMACY AND CHEMISTRY

Report to the Council

The Council has authorized publication of the following report. Nonproprietary terminology is used for drugs that are mentioned; when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations. H. D. KAUTZ, M.D., *Secretary.*

CURRENT STATUS OF THERAPY IN SYPHILIS

Evan W. Thomas, M.D., Albany, N. Y.

The therapeutic agent of choice for all types of syphilis is penicillin, unless a patient is sensitive to penicillin, in which case other antibiotics may be used. The Treponema pallidum is extraordinarily sensitive to penicillin. No proved penicillin-resistant strains of the organism have been found. As a rule, relatively low blood concentrations of penicillin, sustained for 7 to 10 days in early and latent syphilis and for 10 to 20 days in late symptomatic cases, are sufficient to cure or permanently arrest the infection. Rarely, a patient may require more intensive treatment with preparations that provide higher blood concentrations of penicillin sustained over a longer period than is needed for the great majority of patients. Reasons for this are obscure, but it is possible that in rare cases penicillin is absorbed poorly from muscle depots. Whether or not this is true, increasing the total dosage of penicillin for the treatment of syphilis in relatively large series of patients beyond the amount found to be effective in the great majority of cases has not significantly lowered the number of patients who had to be re-treated. Consequently, in the routine treatment of syphilis, there seems to be little reason to exceed total dosages of penicillin that have proved to be adequate in 85 to 95% of cases.

The treatment schedules advised in this article are minimal. They are based on experience with relatively large series of cases that have been followed up for at least two or more years after therapy. It must be recognized, however, that by far the largest series of patients with such a follow-up were treated with penicillin preparations that preceded benzathine penicillin G (Bicillin; Permapen). The advantages of this new preparation are so great that it cannot be omitted from any discussion of modern antisyphilitic therapy. Despite the relatively meager data on prolonged follow-up of patients treated with this very slowly absorbed preparation, it promises to supersede other types of penicillin in the treatment of syphilis. A single treatment with 2,400,000 units of benzathine penicillin G provides demonstrable blood concentrations of penicillin for at least 15 days. Because of the slow absorption, blood levels of penicillin are low but sufficiently high for the treatment of most cases of syphilis, with the possible exception of relapses and infections of the cardiovascular and central nervous systems.

Classification of Syphilis

In outlining the treatment of syphilis, the disease can be classified into three main divisions: (1) early symptomatic syphilis, which includes the primary and secondary stages; (2) latent or asymptomatic syphilis diagnosed solely by serologic tests and history; and (3) late symptomatic syphilis.

Latent syphilis has long been classified as early or late. Early latent syphilis is defined by some authorities as an infection of less than 2 years' duration and by others as one of less than 4 years' duration. Which definition is chosen depends upon how long one believes the immunologic status of early syphilis lasts. Actually the duration of this status probably differs greatly in different individuals, and, for the purpose of treatment, there is no reason to believe that either early or late latent syphilis requires more or different therapy than does secondary syphilis. However, in evaluating the results of therapy, it has been found that early latent syphilis of less than one year's duration usually becomes seronegative after treatment much more rapidly than does latent syphilis of longer duration.

Treatment Schedules for Primary and *Secondary Syphilis*

A single treatment with 2,400,000 units of benzathine penicillin G is advised for routine treatment of early symptomatic syphilis. This dosage is best given by an injection of 1,200,000 units (4 cc.) in each buttock. A single injection of 4 cc. of a preparation containing 600,000 units per cubic centimeter can be given, but this concentrated suspension has caused incapacitating pain at the site of injection in some individuals. Smith and Shafer and co-workers of the U. S. Public Health Service have reported as good results with a single treatment of 2,400,000 units of benzathine penicillin G as with 4,800,000 units or more of procaine penicillin G in oil and aluminum monostearate given in divided doses over 7 to 21 days. Their findings are based on the follow-up of a series of 196 cases.

If procaine penicillin G in oil and aluminum monostearate is used, the advised dosage is 4,800,000 units given in divided doses of 1,200,000 units at intervals of 2 to 7 days. No advantage has been found in giving individual doses smaller than 1,200,000 units, and some

---

Venereal Disease Consultant, New York State Department of Health.

data suggest that better results have been obtained when injections were given at intervals of 2 to 4 days than at longer intervals.

Evaluation of Treatment of Primary and Secondary Syphilis

Quantitative serologic tests for syphilis are of great help in the follow-up of patients treated for early symptomatic syphilis. Seronegative primary cases may become seropositive immediately after therapy, but the tests should again be negative within a month after successful therapy. Cases of primary or secondary syphilis seropositive at the time of treatment should show definite drops in titers within 6 months after successful therapy. Complete seronegativity may not be obtained for a year or more, but as long as the drop in titers to low levels is maintained, re-treatment is unnecessary. Available data on large series of patients indicate that 20% or more with secondary syphilis remain seropositive in low titers (positive in dilutions of 1 to 2 or less) for 1 to 5 years after successful treatment.

Re-treatment is indicated when a rise of titers from previous levels occurs or when clinical relapse is evidenced by lesions of the skin or mucous membranes. In the absence of clinical relapse, a single rise in titers from previous levels should always be confirmed by repeated tests. When serologic titers are determined at weekly or monthly intervals, it is not unusual to find that increases in the titer of a single test are not sustained at subsequent tests. Relapse or reinfection is associated with rapid and marked increases in titers.

As a rule, a reinfection requires no more treatment than an original infection, but a relapse should be treated more intensively with procaine penicillin G in oil and aluminum monostearate rather than with benzathine penicillin G because of the higher concentrations of penicillin obtained with the former preparation.

Treatment Schedules for Latent Syphilis

When diagnosis of latent syphilis is made, asymptomatic neurosyphilis should be ruled out by spinal fluid examination and cardiovascular syphilis by fluoroscopic examination or teleroentgenography. No good evidence exists that latent syphilis, early or late, requires more treatment than does secondary syphilis; therefore, the treatment schedules advised for secondary syphilis may be used for latent cases.

When the diagnosis is doubtful, because of failure to obtain a spinal fluid examination or to rule out cardiovascular involvement, a single treatment with 2,400,000 units of benzathine penicillin G would probably be effective for most patients with asymptomatic neurosyphilis; however, available data are insufficient to decide this question one way or the other. When in doubt, a total dosage of 6 million units of procaine penicillin G in oil and aluminum monostearate given in doses of 1,200,000 units at intervals of 2 to 7 days should provide sufficient therapy for patients with asymptomatic involvement of the central nervous or cardiovascular systems.

Evaluation of Treatment of Latent Syphilis

A noticeable and relatively rapid decline in serologic titers during the first 6 months after successful treatment can be expected when early latent syphilis has been present for less than one year. When the infection has been present for more than one year, prolonged persistence of seropositivity is the rule. Relatively high titers usually decline within one year after treatment, but occasionally it is impossible to obtain low titers by any regimen of treatment. Persistence of positive serologic tests for syphilis for years after treatment of late latent or late symptomatic syphilis does not necessarily mean a continuation of the infection. Treatment for the sole purpose of obtaining negative titers is usually futile.

Indications for re-treatment are the development of symptoms attributed to syphilis or of sustained increases in serologic titers from previous levels. Development of the latter must be determined with caution. Titers are determined by diluting the serum. They are usually reported as positive in undiluted serum or in dilutions of 1:2, 1:4, 1:8, 1:16, and so forth. The practice of doubling the dilution at each successive step may be disconcerting to the physician unless this is understood. A reported titer of positive in dilutions of 1:16 might be positive in dilutions of 1:32 in a subsequent test without the increase being significant; a later test might again be reported as positive in dilutions of 1:16. To be significant, an increase in reported titers should be more than one step in the dilutions and the increase should be sustained for several months before re-treatment is given. In a prolonged follow-up of treated patients, it is not unusual for reported titers to fluctuate at times between lower and higher levels.

Treatment of Late Symptomatic Syphilis

No data are as yet available on the follow-up of significantly large series of patients treated for late symptomatic syphilis with benzathine penicillin G. If this preparation is used, it seems advisable to give at least three treatments of 2,400,000 units at intervals of no more than 7 days. The purpose of this treatment is to increase the concentration of penicillin within the body rather than to prolong the duration of treatment.

Good results have been obtained in the treatment of neurosyphilis with procaine penicillin G in oil and aluminum monostearate. Serial spinal fluid examinations afford means, which are unavailable in cardiovascular syphilis, of evaluating treatment of this complication. On the basis of spinal fluid examinations, total dosages of 6 to 10 million units of this form of penicillin are sufficient for over 90% of all types of neurosyphilis, including paralytic dementia and primary optic atrophy. This does not mean that symptoms caused by irreversible changes in nervous structures can be relieved or that far-advanced cases of primary optic atrophy may not progress to blindness. The time to treat syphilis is before such advanced pathological changes have occurred.

By analogy with neurosyphilis, treatment with 6 to 10 million units of procaine penicillin G in oil and aluminum monostearate can be advised for all types of late symptomatic syphilis. Individual doses, consisting of 1,200,000 units, may be given two or three times a week.

Evaluation of Treatment of Late Symptomatic Syphilis

As is true of late latent syphilis, treatment of late symptomatic syphilis is not followed in most patients by seronegativity within 10 or more years. Regardless of the kind, amount, and duration of therapy, 70% or more of large series of patients treated for late latent and late symptomatic syphilis have been seropositive 10 years after treatment.

Re-treatment is advised when titers increase significantly from previous levels and the increase is sustained for several months. Even in the absence of increased serologic titers, progression or relapse of symptoms and signs attributed to syphilis may be an indication for additional therapy, but it is by no means true that active syphilis is always the cause of such presumed progression. Causes other than syphilis may adversely affect tissues already severely injured by syphilis that has been inactivated by treatment.

The best guide to the activity of neurosyphilis is serial spinal fluid examinations performed at 6-month intervals. Pleocytosis (lymphocytes and other mononuclear cells in the spinal fluid) in association with positive specific tests for syphilis in the spinal fluid indicate disease activity. After treatment, cell counts should be less than 4 per cubic millimeter within 6 months to a year; high total protein content of the spinal fluid at the time of treatment should decline within a similar time, but the total protein determinations may not be within normal limits for a year or more. High titers of specific tests for syphilis in the spinal fluid at the time of treatment should show a decline within one year after treatment, but the tests generally do not become negative for years. Relapse of neurosyphilis is indicated by the reappearance of increased cell counts and frequently by increases in the total protein and in quantitative specific tests for syphilis in the spinal fluid. Titers of the blood serologic tests may or may not increase in the presence of relapsing neurosyphilis.

Unfortunately, a word of caution regarding the reports of cell counts, total protein values, and colloidal gold tests of spinal fluid is necessary. Unless these tests are made with reasonable accuracy and consistency, the reports may be more confusing than helpful. In the absence of complete and reliable spinal fluid examinations for neurosyphilis, patients might well be spared the ordeal of repeated spinal punctures. On the basis of experience at Bellevue Hospital in New York City where spinal fluid examinations were made by specially trained personnel, 6 to 9 million units of penicillin, acting over 15 to 20 days, should inactivate neurosyphilis in over 90% of patients.

Treatment of Syphilis in Pregnancy

Syphilis in pregnant women requires no more or different therapy than in nonpregnant women. The question always arises as to whether the woman who has acquired syphilis should be treated in each succeeding pregnancy. In general, available data indicate that this is unnecessary, provided the woman has received previous penicillin therapy with no subsequent evidence of relapse or reinfection. When there is doubt about the adequacy of previous treatment, a single treatment with 2,400,000 units of benzathine penicillin G or four injections of 1,200,000 units of procaine penicillin G in oil and aluminum monostearate should be given during pregnancy. When syphilis is discovered very late in pregnancy, it is always advisable to treat it as soon as possible. Even when treatment is given only a few days before delivery, the fetus may benefit by the therapy as penicillin crosses the placenta to the fetus.

Treatment of Congenital Syphilis

Congenital syphilis can be treated in the same way as acquired syphilis except that smaller doses should be used in children weighing under 32 kg. (70 lb.). Infants and children should receive total doses of 75,000 to 100,000 units of penicillin per kilogram of weight. Procaine penicillin G in oil and aluminum monostearate in doses of 0.5 to 1 cc. (150,000 to 300,000 units) may be injected every 2 to 4 days until the total dosage is completed.

Substitutes for Penicillin

Antibiotics other than penicillin may be used to treat syphilis in patients sensitive to penicillin. Oxytetracycline hydrochloride (Terramycin Hydrochloride), chlortetracycline hydrochloride (Aureomycin Hydrochloride), chloramphenicol (Chloromycetin), erythromycin (Erythromycin; Ilotycin), erythromycin stearate (Erythrocin Stearate), and carbomycin (Magnamycin) are effective antisyphilitic agents. Data on their use are limited, the greatest experience having been with the first two. Turner and Schaeffer have recently reported that, in the laboratory, T. pallidum is more sensitive to erythromycin and carbomycin than to any of the other antibiotics except penicillin.

It is doubtful that minimal effective dosages of the antibiotics other than penicillin have been determined. From the available data, it appears that early and latent syphilis should be treated orally with at least 3 to 4 gm. daily of oxytetracycline hydrochloride or chlortetracycline hydrochloride for 10 or 12 days. Individual doses of 0.75 to 1 gm. every 6 hours are advised. Late symptomatic syphilis, especially neurosyphilis and cardiovascular syphilis, should be treated with similar doses for at least 15 days. The Mayo Clinic achieved excellent results in the treatment of neurosyphilis with 50 to 90 gm. of chlortetracycline hydrochloride. In giving such large doses, every effort must be made to avoid gastrointestinal symptoms; however, antibiotics should always be preferred to treatment with arsenicals and bismuth. Despite the lack of conclusive data on the use of carbomycin, treatment might well be tried with 2 to 3 gm. of this antibiotic given daily for periods previously suggested.

Summary

A single treatment with 2,400,000 units of benzathine penicillin G can be used for the routine therapy of early and latent syphilis. If procaine penicillin G in oil and aluminum monostearate is used, routine therapy should consist of 4,800,000 units with individual injections of 1,200,000 units every 2 to 7 days. Valid data on the effects of treating late symptomatic syphilis, especially neurosyphilis and cardiovascular syphilis, with benzathine penicillin G are as yet unavailable, but three treatments with 2,400,000 units, with no more than 7 days intervening between each treatment, have been recommended. Good results in the treatment of late symptomatic syphilis have been obtained with total doses of 6 to 10 million units of procaine penicillin G in oil and aluminum monostearate. Individual doses of 1,200,000 units should be given two or three times a week. Patients with syphilis who are sensitive to penicillin can be treated with oxytetracycline hydrochloride, chlortetracycline hydrochloride, erythromycin, or carbomycin. Available data are confined to the first two. Minimal schedules with oxytetracycline hydrochloride or chlortetracycline hydrochloride consist of 3 to 4 gm. daily given in divided doses of 0.75 to 1 gm. every 6 hours for 10 to 12 days in early and latent syphilis and for at least 15 days in neurosyphilis and cardiovascular syphilis. Preliminary reports suggest that carbomycin in daily doses of 2 to 3 gm., for the same periods as advised above, may be effective.

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The enrichment of flour and bread, recommended by the Food and Nutrition Board, National Research Council, and later recognized officially by the Federal Food and Drug Administration, follows certain policies that have long been advocated by the Council. In 1939, the Council announced that it would regard with favor the restorative addition of thiamine and certain other nutrients to white flour and bread. It therefore has been pleased to see the successful application of this policy in the rapidly extending use of enriched flour and enriched bread.

The following report is based on the remarks of Dr. Russell M. Wilder, a former member of the Council and the first chairman of the Food and Nutrition Board, at the dinner honoring Dr. R. R. Williams given by the American Institute of Baking at the Mayflower Hotel, Washington, D. C., April 23, 1956. The occasion recognized the 20th anniversary of the synthesis of thiamine by Dr. Williams and the 15th anniversary of the initiation of the enrichment program. The Council is pleased to authorize publication of this report.

Philip L. White, Sc.D., *Secretary.*

A BRIEF HISTORY OF THE ENRICHMENT OF FLOUR AND BREAD

Russell M. Wilder, M.D., Rochester, Minn.

The practice of making white flour by the process of roller milling was introduced about 1870. Although the texture and color of the white flour produced by this method was a great improvement over the gray, coarse, stone-ground flour, the more refined white flour contained much less of the coatings of the wheat grain and thus less vitamins and minerals. As a result of this process of milling and other changes in the preparation of our food, the amount of thiamine (vitamin B_1) and other so-called micronutrients was reduced in the American diet. From the first, there were critics of the roller-milling process, but after McCollum and Osborne and Mendel revealed the importance to health of these vitamins in the later 1910's, the flour millers and commercial bakers were under constant fire from physicians and nutritionists.

Reliable surveys of the nutritional condition of the people revealed that the average American diet of the 1930's contained only one-third the amount of thiamine as when stone-ground flour was the only flour available. This considerable reduction in the vitamin content of the diet and its deleterious effect on the public health led Dr. R. R. Williams of Bell Telephone Laboratories, New York, to say at a meeting of cereal chemists in New York City in 1939:

> All those are parts of the large problems which the carbohydrate industries face, that of making their staple products more nearly equivalent in nutritive value to the whole seed . . . as it was consumed by primitive man. Whether this is to be done by additions of synthetic materials or by retention of the original nutritive components of the crude food-stuffs is a question for industry to decide. To blink at the scientific facts which will presently become common knowledge, will be suicidal for the commercial enterprises concerned.

Actually, even before 1939 industry was attempting to find an answer to the need for nutritionally better flour and bread. It feared a return to the rough, gray flour of the past, diminished appeal of its products, and a further deceleration of the declining consumption of flour and bread. The persistent demand that all bread be made from wholewheat flour was of great concern to industry, knowing as it did that less than 3% of the buyers had ever found whole-wheat bread acceptable. Serious thought was being given to restitution to white flour of certain fractions removed in milling wheat. Attention was directed to the possibility of returning to the flour the delicate layer of skin of the covering of the wheat seed, the aleurone layer. This layer lies between the bran and the starchy interior of the seed and contains the major portion of the vitamins about which the nutritionists were concerned. In 1936 the synthesis of thiamine by R. R. Williams and J. K. Cline occurred, and it soon became commercially available.

Emeritus Member of the Mayo Clinic.

This was the situation in March, 1939, when the Council on Foods and Nutrition of the American Medical Association encouraged, with some qualifications, fortification of certain staple foods with vitamins and minerals, specifically the restorative additions of thiamine, niacin, riboflavin, iron, and calcium to white flour and white bread. Three events in the summer of 1940 quickened developments. First, the British government proposed to fortify flour with synthetic thiamine. Second, the recently appointed committee on medicine of the National Research Council advised reinforcement with thiamine of all white flour purchased for our military forces. Third, the Federal Food and Drug Administration scheduled public hearings to consider a standard of identity for flour. The recommendation of the committee on medicine was based on that of one of its subcommittees, which also had expressed itself on the need for a reinforced flour for the civilian population. The action of the Food and Drug Administration was in compliance with the new Food, Drug and Cosmetic Act, a law designed to strengthen the earlier food and drug law by setting standards for commodities. The procedure was, and is, to publish a proposed definition of a product and then to hold a public hearing to provide the opportunity for those opposed to the proposal to make known their objections.

TABLE 1.—*Levels of Enrichment for Varieties of Flour*

	Mg./Lb.	
	Minimum	Maximum
Thiamine	2.0	2.5
Riboflavin	1.2	1.5
Niacin	16.0	20.0
Iron	13.0	16.5
[illegible]	500	625
[illegible]	[illegible]	1,000 U.S.P. Units

* Required in self-rising flour, minimum, 500 mg., maximum, 1,500 mg. per lb. Optional in all enriched flours except self-rising.

† Optional

The proposal that was issued defined white flour as that flour which was in common use. This proposal, if adopted, would have closed the door to the improvements recommended by the committees. Physicians and scientists on those committees were disturbed, as were certain millers and bakers interested in and experimenting with the procedure recommended by the American Medical Association. Surgeon General Thomas Parran of the United States Public Health Service had been aroused by recently completed food-consumption surveys, particularly those of the Stiebeling-Phipard study from the Department of Agriculture. He and Dr. M. L. Wilson, director of the extension service, Department of Agriculture, who had recently been chosen to lead a nutrition committee within the government, were convinced that improvement of bread was basic to the effort demanded at that time to improve the nutrition of the people in the interest of national defense.

These hearings on flour were well attended. Many people wanted something done, but no agreement could be reached. Then the leaders of the industries involved met with the scientists concerned several times, and harmony of opinion was obtained for presentation when the hearings were resumed.

The Food and Nutrition Board was established as a part of the National Research Council to provide scientific guidance for the national nutrition program. It first assembled one week after the hearings on flour had been closed but before decisions had been reached. At this meeting the board endorsed the recommendations respecting flour that had been submitted to the Food and Drug Administration, and a committee on cereals was appointed to develop related standards for white bread. The American Bakers' Association and the American Institute of Baking assisted in the preparation of these standards. Finally, in March, 1941, at a meeting in Chicago to which all members of the baking and milling industries had been invited, and also at the National Nutrition Conference for Defense held in Washington in May, 1941, general endorsement of the enrichment program was obtained.

Tables 1 and 2 give the levels of enrichment for flour and bread, as finally stipulated in orders of the Federal Food and Drug Administration.

The levels set for bread are so related to those for flour that bread made from enriched flour will meet them. In actual practice the commercial baker frequently adds the enriching ingredients while making the dough.

Progress

Within a year, nearly all the large commercial bakers and major millers were voluntary enriching their white bread and family flour by adding thiamine, niacin, and iron. Preparations were being made to add riboflavin as soon as it could be made available. To promote the acceptance of these products by the public, pamphlets and posters were distributed by the millions; a major radio program entitled "Listen, America" was developed, and extensive advertising was conducted in newspapers and magazines. Assistance and encouragement came from many other quarters; the enrichment of flour and bread was endorsed by almost all professional organizations concerned in any way with public health. Orders issued by the Army and Navy made enrichment mandatory for flour that was purchased for their use. Promotion was extended by the nutrition councils of almost all the states, by the extension services of the federal and state governments, and by innumerable individuals, including physicians, dietitians, and home economists. Occasional but unimportant objections were raised to this program.

TABLE 2.—*Levels of Enrichment for Bread*

	Mg./Lb.	
	Minimum	Maximum

Riboflavin	0.7	1.6
Niacin	10.0	15.0
Iron	8.0	12.5
Calcium*	300	800
Vitamin D*	150	750 U.S.P. Units

* Optional.

In January, 1943, the first order issued by the newly created War Food Administration included a requirement that all baker's white bread be enriched. The war powers of the president ended with Japan's surrender, but in the meantime legislative action had been started at state levels. The legislature of South Carolina, on the urging of Dr. E. J. Lease and the state's nutrition council, was the first to take such action; the trend continued until 27 of the 48 states, as well as Puerto Rico and Hawaii, now have such legislation.

As a result of the personal efforts of Dr. Williams, the enrichment movement spread to other lands. Since more than three-fourths of the food calories in many countries come from cereals, the need for enrichment is even greater than in the United States. In the Orient, rice predominates in the diet, and it is also milled to whiteness. The preference of most consumers for white rice is insurmountable, and in torrid climates brown rice becomes rancid and infested quickly. Enrichment solves these problems, but the costs involved, small as they are, become significant in impoverished populations.

Enrichment of white flour was made compulsory in Newfoundland in 1944. The local government was so impressed with the benefits that continuation of the program was made a condition of annexation to Canada in 1949. Enrichment was prohibited in Canada at that time, but in 1953 the practice became permissible. The occasion was celebrated by a series of conferences across the Dominion. At the first of these, in Toronto, Dr. James McGrath, of the Ministry of Health of Newfoundland, made this comment: "Flour enrichment is still compulsory in Newfoundland. It is now permissible on a voluntary basis for the rest of Canada. . . . I will venture one prediction: that the benefits of enrichment are so evident that it will not be long before the use of enriched flour on a voluntary basis will be as extensive in the rest of Canada as it is now in Newfoundland where it is compulsory." This prediction has now become a reality.

During the war years in Great Britain, use of 85% extraction flour was compulsory. Later, the permissible extraction was lowered to 80%, meaning 80 parts of flour from every 100 parts of wheat. Use of 80% extraction flour is now encouraged by a subsidy, but white flour (72% extraction, or even less) can be sold; however, such low-extraction flour must be enriched with thiamine, niacin, and iron to the levels of 80% extraction flour. Not only are the levels lower than those in the enrichment formula used in the United States but there is no requirement for the addition of riboflavin. In Denmark, on the basis of conclusions reached by the Danish Academy for Technology, a government order was issued in December, 1953, requiring that all white flour, farina, and semolina offered for sale or delivery in Denmark contain 5 mg. of thiamine, 5 mg. of riboflavin, and 30 mg. of iron per kilogram of the respective material. In Sweden, most white flour is enriched with thiamine, riboflavin, niacin, and iron on a voluntary basis. In Germany and France there is practically no enrichment of flour or bread, but in Holland, Belgium, Switzerland, and Italy enrichment of flour is voluntary. In much of South America enrichment of wheat flour and other cereals is under discussion, but in Chile enrichment of all white flour has been mandatory for a year or more.

Benefit to Public Health

Those engaged in our enrichment program have repeatedly emphasized that the purpose of enrichment is to help correct certain defects in the diet. To make white bread a better food, desirable as that might be, is secondary to the use of flour and bread as vehicles for effecting an increased consumption of certain micronutrients. This has been accomplished. After enrichment of bread and flour became general, the average diet contained not only additional iron but almost twice the amount of thiamine, riboflavin, and niacin as before.

The enrichment program has played an important role in the disappearance of the frank deficiency diseases, beriberi and pellagra. For example, among 10,000 recent admissions to the Hillman General Hospital in Birmingham, Ala., not one patient with pellagra was found—this in an area in which pellagra previously had been rampant. At a large general hospital in Chicago, in which beriberi previously could always be observed, a 3-year search failed to reveal a single case of beriberi. In 1948 and 1949 a survey conducted among some 16,000 inmates of the Chicago House of Correction revealed only two cases of pellagra, three of ariboflavinosis, and no beriberi. A point of interest in this Chicago study was that the decline in the prevalence of these vitamin deficiency diseases started very shortly after the beginning of enrichment of bakery bread in Chicago. Between 1946 and 1950, a number of nutrition surveys were conducted in various areas of the country; surveys of family groups, of factory workers, of school children, and of others detected only an infrequent case of frank deficiency disease.

The benefits accruing from enrichment are by no means limited to prevention of the frank deficiency diseases. Some time ago I was engaged with others in extensive studies of the clinical effects of experimental diets low in thiamine. The studies yielded most convincing evidence that deficiency of this vitamin, to a degree insufficient to provoke frank beriberi, would produce disturbances of the psyche. Before enrichment was initiated, many diets in this country were low enough in thiamine to cause such effects. Even today, when enrichment of bread and flour is in general but not in universal use, a definite proportion of the people are probably subsisting on diets that are borderline in content of thiamine. To relax our efforts now would therefore be unfortunate.

A wealth of research and practical experience has proved the value of enriched bread in the diet of persons of a distinctly suboptimal nutritional status. Enriched bread is also believed to serve a purpose in diets that approach adequacy.

Although the enrichment program stemmed from the work of a great scientist, much credit for the success of the program should be given also to the pharmaceutical manufacturers of the micronutrients required. Tremendous quantities were called for at the lowest possible costs. These have been supplied at costs so low that the miller and commercial baker have been able to enrich their flour and bread at little or no additional expense to the consumer.

The flour and baking industries have voluntarily continued this program, whether or not state laws required it. Consequently, every person in this country is able to obtain this better bread, regardless of whether his residence is in one of the 27 states that make enrichment mandatory.

ANGINA PECTORIS—A THIRTY-YEAR PROGRESS REPORT

GUEST EDITORIAL

Arthur M. Master, M.D.

Only one generation ago, the diagnosis of "angina pectoris" was tantamount to the issuance of a death warrant. At that time, the severe, frequently excruciating pain that the patient suffered, the little understood prevention of the disease, and the condition's inadequate treatment engendered fears that could not reasonably be dispelled. In addition, cases of sudden death or severe heart attacks preceded by chest pain with normal three-lead electrocardiograms, i. e., no Q waves or RS-T segment elevations, were also considered episodes of angina pectoris. We now know that these were, for the most part, attacks of myocardial infarction due to complete obstruction of a coronary artery (occlusion) or bouts of prolonged severe myocardial ischemia without complete closure (coronary insufficiency). This added to the terror of the term angina pectoris. Today, in the light of recent advances and newer concepts in the prophylaxis of the disease and in its therapy, such an irrational approach to angina is not justified. Because the term angina pectoris is still so emotionally charged, however, it should be abandoned and a more descriptive, neutral label such as "chest pain due to coronary artery disease" should be employed.

The agonizing dread associated with the angina of 30 years ago was largely contributed to by the then existing economic and psychological factors. Social security, unemployment insurance, and adequate compensation laws had not as yet been enacted. Absence from work, for whatever reason, usually meant loss of pay. Mild attacks of angina, therefore, went unheeded. The sufferer necessarily continued on the job, simply for fear of losing it and his livelihood. Because both patients and doctors alike believed that the disease was clinically hopeless, early symptoms were often deliberately concealed from the family, the employer, and even the physician. When medical advice was finally sought, the condition was already full-blown. The late diagnosis of the majority of cases and the almost universal inadequacy of their treatment enhanced the general impression that angina pectoris was totally and permanently disabling. Undoubtedly the majority of patients given diagnoses and treated were in an advanced stage of their disease.

Only one generation ago, a definite diagnosis of angina pectoris was made only if the classic pattern of symptoms, described by Heberden in 1768, was present. It was necessary that the pain be crushing and vise-like in character and that it be associated with a "fear of impending death." It was necessary that the pain be substernal and that it radiate to the back, the jaw, or down the inner aspect of the left arm to the little and ring fingers. It was necessary that the pain invariably follow exertion, excitement, or emotion and that it be immediately relieved by amyl nitrite or glyceryl trinitrate (nitroglycerin). We now know that all these classic symptoms occur in only a minority of cases, and that any single one of them may be absent. Thus, severe coronary artery disease may produce only a dull ache. This may be precordial rather than substernal. The pain need not radiate down to the ulnar aspect of the hand. Indeed, it may not radiate at all from the site of its maximum intensity. It may not be precipitated by exertion; walking at even a good pace may not produce any discomfort. It may not be relieved by glyceryl trinitrate.

Formerly, a normal three-lead resting electrocardiogram was accepted as evidence that the chest pain was of noncardiac or psychogenic origin. Despite very suggestive clinical findings, the patient was frequently given a reassuring pat on the back and told not to worry. A subsequent heart attack occurred as a great surprise, especially to the physician, who attributed it to the natural vagaries of angina. Today, even a normal 12-lead resting electrocardiogram does not necessarily exclude the diagnosis of coronary artery disease, if the clinical history points to its presence. It is merely a reflection of the heart's ability to cope with the work load during the resting state. It is not an indication of the capability of the heart to meet the stress and strain of routine living. In an attempt to obtain this vital information, the Master two-step exercise test was devised.

When three or four of the characteristic features of angina, as described by Heberden, are present—the nature of the pain, its location, its radiation, and its precipitating factors—a diagnosis of a classic attack may usually be made. However, one or two of the features may be found in conditions other than coronary artery disease and may be absent in 10 to 40% of the cases of angina pectoris. An awareness of the possible variations of the clinical picture will make for more accurate diagnosis of coronary artery disease.

Thirty years ago, an anginal attack was treated with amyl nitrite perles. Often whiskey (spirituous liquors) was advised, because Heberden in 1768 had noted its soothing effect. Xanthines and theophylline were prescribed as coronary vasodilators, on the basis of experimental findings in the dog. Tobacco, even in small amounts, was taboo. Glyceryl trinitrate, for some unknown reason, was prescribed only when the pain was very severe, as if to suggest that its use signified the

---

Consulting Cardiologist, the Mount Sinai Hospital, New York.

hopelessness of the condition. The usual dose was 1/100 grain (0.6 mg.), repeated frequently or until it relieved the pain.

The entire prophylactic, therapeutic, and psychological approach to angina has been much improved in recent years. Amyl nitrite is no longer routinely used in place of glyceryl trinitrate, because it produces a much more marked generalized vasodilation. The xanthines are not as frequently prescribed as formerly, having largely been replaced by coronary vasodilators such as pentaerythritol tetranitrate. There has been a major change in our use of glyceryl trinitrate; it is now employed not only in the treatment of the acute attack of angina but also in its prevention. Any pain-provoking stimulus that cannot be avoided is anticipated by the use of the drug prophylactically. When activities known to precipitate an anginal attack are undertaken —coitus, walking uphill, walking after a meal, walking early in the morning, stepping out into the cold, or walking against the wind—the patient is urged to take glyceryl trinitrate beforehand. Formerly, those who could afford it were encouraged to move to a warm climate. The intelligent use of glyceryl trinitrate prophylactically, however, usually obviates the need for such a move. The predictable prevention of anginal attacks eliminates much of the worry and despair formerly associated with the disease. The patient is more confident and the physician more optimistic, because both believe that angina pectoris is not a hopeless condition. Indeed, remissions do occur.

The dosage of glyceryl trinitrate is not as inflexible as it formerly was. Instead of the former routine 1/100 grain, the initial prescribed dose is often 1/200 grain (0.3 mg.) at present. Amounts even as small as 1/400 or 1/800 grain (0.15 or 0.075 mg.) may be effective. The dose required to relieve a particular patient is usually fairly constant; this dose may be repeated only once within a few minutes if the pain is not relieved by the first tablet. Should the second dose also be inefficacious, it may be wise to reevaluate the case lest acute coronary insufficiency or occlusion be overlooked, aggravated, or produced.

Formerly, as a last resort, patients with status anginosus were subjected to subtotal thyroidectomy. Today, similar effects may be obtained by the relatively innocuous administration of radioactive iodine. Occasionally, cardiopericardiopexy, internal mammary artery transplants, and other surgical procedures may yield good clinical results. Thirty years ago, these techniques were unknown. Stellate ganglion and thoracic sympathectomy or paravertebral blocks were attempted to secure relief from pain.

Tobacco is no longer banned in all cases. Its proscription depends on its effect on the patient's well-being. There is little point in forbidding a tense patient to smoke a little, if that serves to relax him. No longer is a patient allowed to drink excessively. If, however, one or two drinks a day serve to relax an otherwise apprehensive person, it would be unwise to prohibit them. Larger doses of alcohol actually overwork the heart and produce overweight. It was formerly thought that alcohol and tobacco in combination were good, since the former dilated the coronary vessels, which the latter constricted. This view is no longer accepted. It is now believed that a combination of alcohol and tobacco in less moderate doses actually aggravates the anginal syndrome.

Formerly, in patients with coronary artery disease, a major operation for some unrelated condition was considered to be very dangerous. All elective operations were barred by most cardiologists, and only last-resort procedures were permitted. Some of us have always advocated the removal of any focus of infection or irritation that may have a deleterious effect on the well-being of the patient with angina. A common example of the quandary in which physicians and surgeons found themselves was the problem of dealing with cholelithiasis. If gallstone colic developed, I have always recommended early extirpation of the gallbladder. Today, with the improved techniques in anesthesia and surgery, this attitude is more than ever justified. A state of anoxia is avoided, even for short periods, by the use of high concentrations of oxygen, by adequate pulmonary ventilation, by maintaining the blood pressure at an adequate level, and by promptly replacing the blood lost during the operation. As a result, patients with coronary artery disease tolerate surgical procedures extremely well.

Years ago, physicians hesitated to permit a patient with heart disease to fly. Today, however, with pressurized cabins and anti-motion-sickness drugs, there is no greater contraindication to flying than there is to use of any other form of transportation. Travel by airplane may even be preferable, since it obviates the long and often tiring trips by automobile, rail, and sea. The President's recent illness in Denver has again raised the question of whether persons with heart disease should live at high altitudes. I feel that most persons can "acclimatize" themselves to this environment after a period of time but that undue physical exertion should initially, at least, be avoided in an oxygen-poor atmosphere.

Despite all these improvements in therapy, the major change in the status of coronary artery disease in our age has been one of approach. While the pathophysiology is by no means completely understood, we now know that arteriosclerosis is not an inevitable process of aging. Timothy O'Leary, 20-odd years ago, found cholesterol abscesses in intimal plaques. Hence, a fat-poor diet was advocated as part of the treatment, but at that time little attention was given to this suggestion.

Today, it is realized that arteriosclerosis is a disease like any other. It is self-limited and, probably, a manifestation of some derangement of normal lipid metabolism. It may be affected by dietary and other factors. As a result, there has been an unparalleled surge of research in human and animal biochemistry. A renewed confidence has been born, as the result of a better understanding of arteriosclerosis and a hopeful approach to its prevention and cure. This has stimulated a more optimistic outlook among patients and physicians alike. Today, the designation "chest pain" or "coronary disease" is no longer a stigma. Its presence rightly generates caution, but not panic. Government and private agencies are making suitable jobs available for persons with arteriosclerotic heart disease.

The choice is no longer between working 60 hours a week or not at all. Jobs at lighter work, for 35 hours a week, or less, can now be found. The widespread interest and candid discussion of the President's recent coronary occlusion have made the condition further socially acceptable. Iatrogenic cardiophobia is on the wane. No longer is the patient—be he a well-known industrialist, a mill worker, or a doctor—reluctant to be seen in the consulting room of the cardiologist. The bank president or insurance executive no longer leaves by the back door of the doctor's office. To discuss one's electrocardiogram is as acceptable as to discuss one's analyst.

Until the ultimately inevitable specific prevention and treatment of coronary artery disease have been developed, general supportive measures remain of great importance. The patient who is overweight or obese is firmly advised to reduce. Ataraxics and sedatives are given to decrease tension. These measures, together with a confident outlook, will prolong the life of the patient. Thirty years hence, it is likely that enzymes, hormones, and other perhaps as yet unidentified biochemical agents will make angina pectoris a truly rare condition.

FIRST U. S. INTERNATIONAL MEDICAL FILM EXHIBITION

Each year the Film Library of the American Medical Association receives many unsolicited requests for medical films from physicians, medical societies, medical schools, and government agencies in various countries. Assistance is also requested in selecting top U. S. films to be shown abroad during international meetings of medical and scientific groups. It is evident that films from this country are in demand; and, conversely, we are anxious to see the results of medical advancements in other countries. What better way can this information be transmitted than by the use of a motion picture, which, along with its pictorial presentation, can carry explanations and comments by the man or men who did the work? Even without translation, medical and surgical films can speak an international language. Anatomy and physiology do not change at the border of a country. This comment was made following a recent medical meeting with international attendance: "It was good to see that, once more, 16-mm. films proved to be a unique medium for surmounting the language barriers that too often isolate professional workers attending congresses."

There is ample evidence to state that, first, the medical motion picture is an important force in communicating medical information at all levels; second, the arts and practices of medicine are global in their application and responsibility; and, third, the medical service, to which both of these apply, should be charged with the need to open all possible avenues to spread world wide the tools and techniques available to make the physical and emotional health of man the precursor to the ideal thought of as "the better world." But, in order to encourage and stimulate the flow of medical and scientific films on an international basis, the present import and export procedures must be simplified by government officials the world over. Some efforts have been made in this direction by UNESCO; and some countries, including the United States, are now thinking in terms of a customs simplification act. However, there is much more work to be done by all concerned if the barriers still existing to a practical exchange of such films are to be broken down further. Often numerous and complicated forms are required to secure the duty-free return of films that have been temporarily loaned to a colleague in another country. There are long delays and time-consuming procedures in clearing with customs—to say nothing of the expense in both time and money.

Why should not medical and scientific films, which are just another medium of communicating scientific information, be granted the same opportunity as books and printed materials to contribute to the education of physicians and surgeons in every country of the world?

This question along with others will be discussed at meetings scheduled to be held in connection with the International Film Exhibition. This exhibition, sponsored by the American Medical Association, in cooperation with Johnson & Johnson, will present an outstanding collection of foreign-made medical and surgical films as a special feature of the 106th Annual Meeting of the American Medical Association in New York, June, 1957.

Apart from the regular film theater, which will show the new and outstanding films produced in the United States, a theater will be devoted exclusively to the showing of these special films representing some of the outstanding medical research work being carried on in other countries. All films of distinction selected for showing will be translated and presented in English. This is the first time such a film presentation has been attempted in the United States.

In addition to the film exhibition, there will be ample opportunity for foreign guests and others interested to discuss the problems involved in the international exchange of medical films.

AID FOR HUNGARIANS

The Board of Trustees of the American Medical Association at its recent meeting in Seattle appropriated $5,000 to aid in the care of Hungarian refugees who are fleeing to Austria. The courage of these unfortunate people is known throughout the world, and to those who live in more fortunate countries it becomes a symbol for the men and women who believe enough in freedom to fight for it. Elsewhere in this issue of THE JOURNAL (page 1568) are two letters from the executive secretary of the American Medical Society of Vienna, a society known to physicians all over the world who have visited its headquarters. The executive secretary of the society has had, because of these responsibilities and others, a unique opportunity to see firsthand the plight of the fleeing people. He and his colleagues also through personal experience know the need for aid and how to meet the need during this time of urgency. Regardless of the size of the contribution it will be welcome.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

SUPPLEMENTARY LIST–CORRECTIONS

In the annual Internship and Residency Number of The Journal, Sept. 22, 1956, incomplete or inaccurate data were presented. The corrected entries are as follows:

APPROVED RESIDENCIES AND FELLOWSHIPS

ANESTHESIOLOGY

Name of Hospital	Chief of Service	Total Anesthetics	Inhalation Anesthetics	First Year Residencies Offered*	Total Residencies Offered*	Beginning Stipend (Month)
Bronx Municipal Hospital Center [1-3], New York City	L. R Orkin	103	70	10	21	$105

HOSPITALS APPROVED FOR RESIDENCY TRAINING

The following hospitals should be listed under "Hospitals Approved for Residency Training" as follows:

Butterworth Hospital * Grand Rapids, Mich..	Anes., Int. Med., Ob.-Gyn., Path., Ped., Rad., Surg
Sacred Heart Hospital * Spokane, Wash.	*Gen'l Pract., Ob.-Gyn., Path., Rad., Surg.*

BUREAU OF MEDICAL ECONOMIC RESEARCH

SOME CATEGORIES OF PATIENTS TREATED BY PHYSICIANS IN HOSPITALS

Frank G. Dickinson, Ph.D.
and
James Raymond, M.A., Chicago

The Bureau of Medical Economic Research of the American Medical Association has a number of studies under way that are designed to produce an estimate of the totality of services rendered by physicians to the American people annually.[1] The first item in this series presented data on the age and sex distribution of patients treated by physicians in hospitals; the excess of male patients in the hospitals in the United States on a given day was surprising.[2] The present study considers hospital patients only in selected categories chosen because each includes a large number of patients and because it was reasonable to expect that hospital administrators and medical record librarians could furnish the necessary data for the entire year of 1954. We wish to express our deep appreciation to the hospital administrators, the medical record librarians, and other hospital staff members for their cooperation in a difficult undertaking. The next study will deal with the role of accidents in the services of physicians to their hospitalized patients. Subsequent studies in the series will involve estimates of the numbers of patients seen by physicians in the home and in the office as well as of patients in all diagnostic groups seen during a selected week in all hospitals. When this series is completed several years hence, the Bureau will have presented a rough estimate of the totality of the services rendered annually by physicians to the American people. It will then be possible for the first time to present a counterpart to the total expenditures of the people for medical care—the value side as well as the cost side of physicians' services. In other words, this series of studies is designed to describe what we get in terms of ailments treated for what we spend for physicians' service.

Moreover, these studies should provide much additional information on morbidity, for which nationwide data are deficient in both quality and quantity. Measures of the volume of medical care—other than dollar totals—and its components are incomplete in many fields. For instance, although information is available on the contagious diseases for the nation as a whole, there are only sampling studies of total morbidity for selected areas, and these are for limited periods of time.[3] Thus, the available national data on the contagious diseases demonstrate a highly significant decline in the incidence of diphtheria and scarlet fever in the last 25 years, but the decline in the number of mastoid operations performed by physicians, well known to older members of the profession, is not similarly demonstrable through statistical measures. This lack of comparative morbidity data and of quantified data on operations and other treatments presents many difficulties to those who would compare the past with the present in order to plan for future developments in the field of medical care, including methods of budgeting and payment.

Organization and Scope of Study

So many complications have developed in the preparation of this report, as well as in the survey itself, that it seems wise to present two reports. This article will be reprinted without additions from THE JOURNAL as Bulletin 102 of the Bureau of Medical Economic

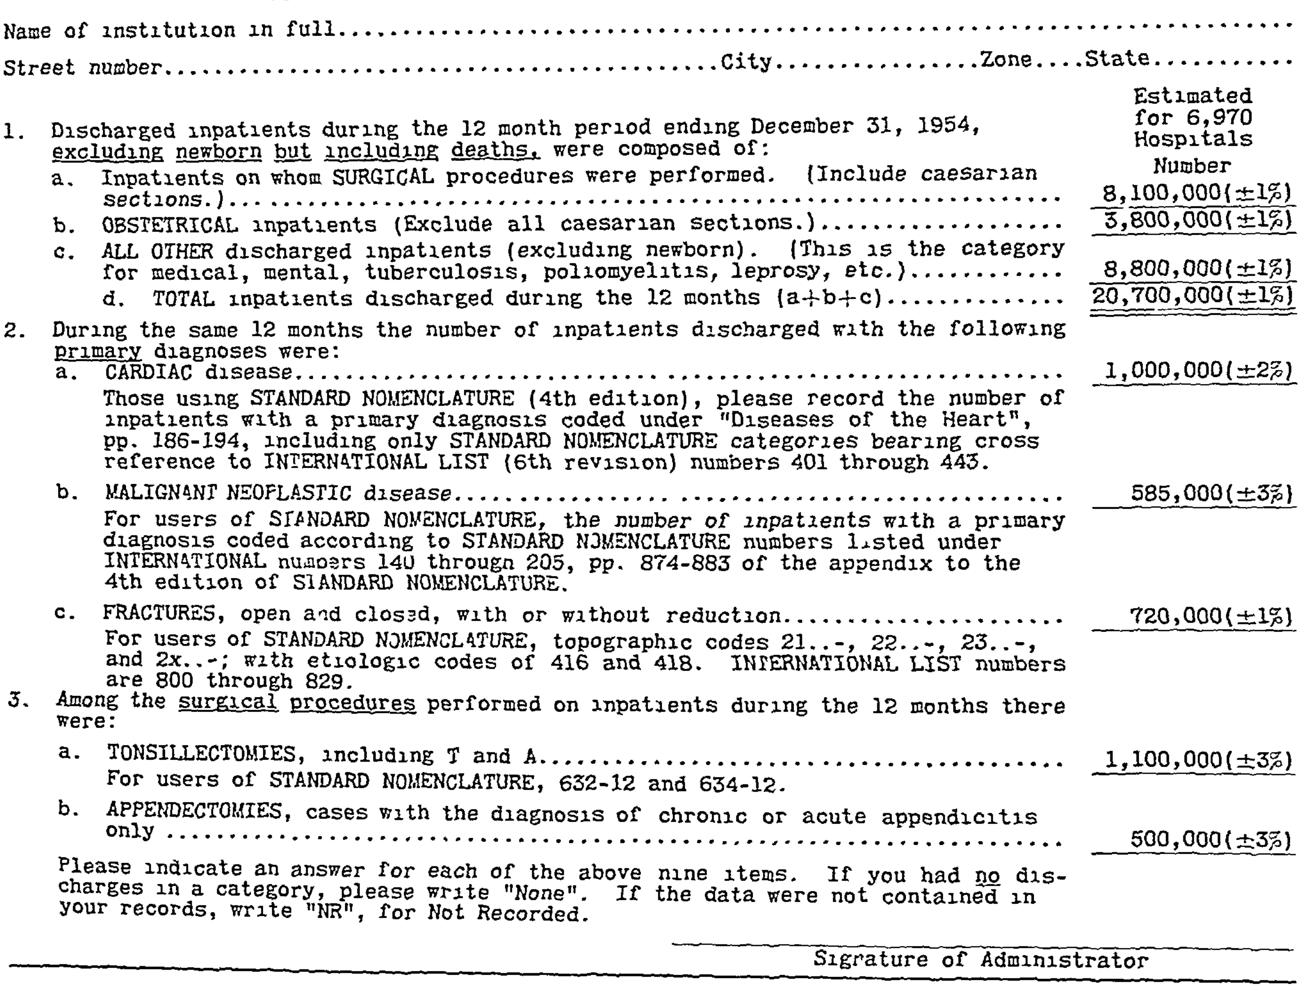
---

Director (Dr. Dickinson) and Staff Associate (Mr. Raymond), Bureau of Medical Economic Research, American Medical Association.

Research. Its companion, Bulletin 102A, supplement to Bulletin 102, will contain the appendix tables not presented herein and some discussions of alternate procedures for making national estimates. The two items will probably be bound together.

It was early determined that the scope of the present study would be restricted to hospital inpatients classified according to some of the most common diagnostic categories of inpatients discharged from 6,970 hospitals accepted for listing by the American Hospital Association in 1954. The rather general and, hence, limited scope of the study is most succinctly circumscribed by an examination of the survey questionnaire and of the results obtained, both of which are presented in the chart

CHART 1.—*Estimated Data (Rounded) for 6,970 Hospitals Accepted for Listing by the A H A. in 1954*



SECTION III--STATISTICAL STUDY--AMERICAN MEDICAL ASSOCIATION

Name of institution in full...

Street number...City................Zone....State...........

	Estimated for 6,970 Hospitals Number
1. Discharged inpatients during the 12 month period ending December 31, 1954, excluding newborn but including deaths, were composed of:	
a. Inpatients on whom SURGICAL procedures were performed. (Include caesarian sections.)........	8,100,000(±1%)
b. OBSTETRICAL inpatients (Exclude all caesarian sections.)........	3,800,000(±1%)
c. ALL OTHER discharged inpatients (excluding newborn). (This is the category for medical, mental, tuberculosis, poliomyelitis, leprosy, etc.)........	8,800,000(±1%)
d. TOTAL inpatients discharged during the 12 months (a+b+c)........	20,700,000(±1%)
2. During the same 12 months the number of inpatients discharged with the following primary diagnoses were:	
a. CARDIAC disease........	1,000,000(±2%)
Those using STANDARD NOMENCLATURE (4th edition), please record the number of inpatients with a primary diagnosis coded under "Diseases of the Heart", pp. 186-194, including only STANDARD NOMENCLATURE categories bearing cross reference to INTERNATIONAL LIST (6th revision) numbers 401 through 443.	
b. MALIGNANT NEOPLASTIC disease........	585,000(±3%)
For users of STANDARD NOMENCLATURE, the number of inpatients with a primary diagnosis coded according to STANDARD NOMENCLATURE numbers listed under INTERNATIONAL numbers 140 through 205, pp. 874-883 of the appendix to the 4th edition of STANDARD NOMENCLATURE.	
c. FRACTURES, open and closed, with or without reduction........	720,000(±1%)
For users of STANDARD NOMENCLATURE, topographic codes 21..-, 22..-, 23..-, and 2x..-; with etiologic codes of 416 and 418. INTERNATIONAL LIST numbers are 800 through 829.	
3. Among the surgical procedures performed on inpatients during the 12 months there were:	
a. TONSILLECTOMIES, including T and A........	1,100,000(±3%)
For users of STANDARD NOMENCLATURE, 632-12 and 634-12.	
b. APPENDECTOMIES, cases with the diagnosis of chronic or acute appendicitis only........	500,000(±3%)

Please indicate an answer for each of the above nine items. If you had no discharges in a category, please write "None". If the data were not contained in your records, write "NR", for Not Recorded.

Signature of Administrator

The chart is a copy of the survey questionnaire with approximate totals for all hospitals inserted in the answer spaces. After a discussion of the chart the remainder of this article is largely devoted to the replies received and estimates for the hospitals that did not reply.

Estimated Totals for the 6,970 Hospitals

As indicated by the title, "SECTION III—STATISTICAL STUDY—AMERICAN MEDICAL ASSOCIATION," this schedule was a part of the joint A. M. A. and A. H. A. survey of hospitals for 1954. Other results of this joint survey have been reported in two parts.[4] It will be at once noted from the questions asked in this study that yearly totals of discharged inpatients in certain diagnostic categories were called for; information was not requested on the age, sex, or length of stay of these inpatients nor on the number and variety of specific procedures performed on them by their physicians while they were in the hospital. The totals presented in the chart are approximations, the plus-or-minus variation is indicated after each total. They are approximations because not all of the 6,970 hospitals accepted for listing in 1954 by the A. H. A. replied to this particular questionnaire in whole or in part, making it necessary for estimates to be made for the nonreplying hospitals Moreover, the two operative procedures specified were rarely performed in certain specialized types of hospitals such as the 596 nervous and mental and 393 tuberculosis hospitals.

Question 1.—The first question was designed to obtain the number of inpatients discharged during the calendar year 1954, excluding newborn infants but including patients who died. The total number of inpatients discharged is set forth in *1d* of the chart as the sum parts of *a*, *b*, and *c*; discharged inpatients treated by physicians in hospitals during calendar year 1954 totaled 20,700,000 (± 1%). The admissions to these same hospitals reported by the A. H. A. for the 12 months ending Sept. 30, 1954, totaled 20,345,000 pitals within that category. Third, when the number of discharges reported by the replying hospitals in any subcategory was treated as a percentage of total discharges given by the replying hospitals, the resulting percentage pattern was almost exactly the same as that for admissions to the replying hospitals [col. (7) compared with, col. (4)]; the greatest variation was 0.1 percentage point. Variations in admissions and discharges were similar, and, as noted, they were of similar magnitude. Fourth, the discharges reported by all replying hospitals were 1.5 percentage points, or 240,592, more than the admissions to the same hospitals [see col. (8)]. For only the general and special hospitals the discharges were 1.7 percentage points (258,944) in excess of their admissions; discharges from the mental and tuberculosis hospitals were 6.3 percentage points (18,352) fewer than their number of admissions.

Some small fraction of the excess may be due to the fact that the reporting period for discharges includes three more recent months than the A. H. A. reporting period for admissions. While available data show a clear tendency for the number of hospital admissions to rise over a period of several years, the data do not permit the calculation of any very reliable monthly rate of increase; this is because the number of reporting hospitals has varied each year and because even those hospitals that have reported consistently have been subject to local fluctuations and changes in the demand for their service. It is probable that some of the 1.5% excess of discharges over admissions is due to reporting errors of several varieties. In the editing of the returned questionnaires, a check of the number of discharges reported by each hospital against the number of admissions reported to the A. H. A. was made; when the two figures differed by 20% or more, letters of inquiry obtained many replies to the effect that the hospitals had failed to exclude newborn infants, as directed, from the count of discharged patients. Very probably there were other hospitals for which the figures differed less than 20% that also failed to exclude newborn infants, but we gave them no opportunity to correct their reporting error. Other hospitals stipulated that the number of discharges reported to the Bureau was correct but that the number of admissions reported to the A. H. A. was in error. The cumulation of these and other errors may account for some of the difference.

The fact that admissions and discharges matched as closely as they did is of major significance for this study. For the general and special hospitals at least, we are justified in regarding admissions and discharges as being of practically the same magnitude. Moreover, the mental and tuberculosis hospitals had only 1.9% of the admissions and only 1.7% of the discharges reported upon here. There is, therefore, little reason to believe that the percentages of discharges for each section of the questionnaire, reported in the following paragraphs, are distorted by the use of number of discharges, rather than admissions, as a base.

Estimates for Nonreplying Hospitals

Because some groups of hospitals did not reply in the same proportion as the total, 62.1% of all replying hospitals, it was concluded that estimates should be based upon that factor wherein the greatest amount of representativeness was obtained—undoubtedly admissions (76.5%)—and that estimates should be made for as many different classes of hospitals as possible. Accordingly, estimates were prepared for each of the 11 classes of hospitals shown in tables 1 and 2 (11, because there are no mental and tuberculosis hospitals in the subcategory "Federal-Military") based on the ratios of the number of admissions in the nonreplying hospitals to the number of admissions in the replying hospitals. A second set of computations utilized the ratios of number of beds, and a third set was based on these ratios for average daily census. Primarily because the estimates based on numbers of admissions gave an estimated total number of discharges from all 6,970 hospitals that varied by the smallest amount from the known numbers of admissions to these hospitals, these are the estimates reported here. The estimates appearing in the chart are based primarily on admissions, and the range above and below the number entered indicated by the percentage in parenthesis is broad enough, in most cases, to encompass the higher and lower estimates based on beds and average daily census. Appendix tables show the somewhat larger estimates resulting when the

TABLE 2.—*Comparison of Admissions and Discharges, by Hospital Type of Service and Type of Control, 1954*

* No military hospitals in this category

hospitals were classified according to size or regional location and when the rates for number of beds and/or average daily census were used. We definitely prefer the estimates based on admissions.

Four different ratios were computed and used in estimating the numbers for the nonreplying hospitals in question 2 and 3. This was necessary because not every one of the 4,329 hospitals that answered question 1 replied to all parts of questions 2 and 3. Indeed, it was not expected that question 2—dealing with discharged inpatients having the primary diagnoses of cardiac disease, malignant neoplastic disease, or fractures—would be applicable to the mental and tuberculosis hospitals; so the basis of estimation here became the number of admissions to only the six groupings of the 5,981 general and special hospitals. There were 2,909 general and special hospitals that answered part *a* of question 2 (cardiac disease), 2,961 that answered part *b* (malignant neoplastic disease) and 3,227 that answered part *c* (fractures). This meant that three different sets of ratios of admissions in nonreplying to replying hospitals had to be computed. As for question 3, the numbers of tonsillectomies and appendectomies performed in the replying mental and tuberculosis hospitals were, while not large, of sufficient size to warrant the consideration of this question as applicable to all hospitals and, hence, to permit estimation of nonreplies on the basis of the total admissions to all 6,970 hospitals. There were 570 mental and tuberculosis hospitals among the 4,088 hospitals that gave usable answers to question 3.

Three Groups of Inpatients Discharged

The replying hospitals reported that they discharged 15,810,084 inpatients during 1954; 271,762 were from mental and tuberculosis hospitals. Inpatients on whom physicians performed some surgical procedures numbered 6,238,660 of these discharges; through projection this number was raised to 8,106,134 (rounded to 8,100,000 on the chart) for all hospitals accepted for listing by the A. H. A. in 1954. The replying hospitals reported 2,902,865 inpatients classified as obstetric among their total discharges for the year, and it was estimated that 884,322 more such patients were discharged from the nonreplying hospitals; thus the projected total was 3,787,187 obstetric inpatients discharged (rounded to 3,800,000 on the chart) for the year. The A. H. A. census reported 3,342,599 births in 4,869 hospitals during the year ending Sept. 30, 1954. Only 5,800 of the reported obstetric patients were from mental and tuberculosis hospitals; and the estimated total for all mental and tuberculosis hospitals was only 7,979. (Of the 5,666 obstetric discharges reported by local government hospitals in the mental and tuberculosis category, 5,644 were reported by Herman Kiefer Hospital in Detroit (east north central region). This hospital, coded as a tuberculosis hospital on the A. H. A. punch cards, has large maternity and isolation sections. The A. H. A. data on this hospital for the year ending Sept. 30, 1954, are 1,450 beds, 8,636 admissions, 1,118 average daily census, and 4,855 births. This hospital reported, for the year ending Dec. 31, 1954, 1,594 surgical, 5,644 obstetric, 1,345 "other," and a total of 8,583 discharges, plus 3 tonsillectomies and 9 appendectomies.) The total reported for the third group, "All other" (part *c*, question 1), was 6,668,559 discharges; the total reported for the three groups was 15,810,084 discharges. The "All other" cases were increased to 8,762,106 (rounded to 8,800,000 on the chart) when the estimates for the nonreplying hospitals were included; and the total estimated inpatient hospital discharges for the calendar year 1954 was 20,655,427 (rounded to 20,700,000 on the chart). The results of the survey, together with the estimates for the nonreplying hospitals, are shown in table 3. This summary is derived from appendix tables, some of which show the computations of estimates for the nonreplying hospitals.

Of somewhat greater interest than mere numbers are percentages of all discharges accounted for in each diagnostic category—parts *a*, *b*, and *c* of questions 1 and 2 and parts *a* and *b* of question 3. These percentages were obtained by dividing the reported number of inpatients in a diagnostic category by the reported total inpatients discharged from the hospitals that answered that particular question. (The replies to each item in the questionnaire from the general and special and from the mental and tuberculosis hospitals, their total discharges, and the resulting percentages, are shown in table 4.) Inpatients upon whom their physicians performed some surgical procedures were nearly two-fifths (39.4%) of the inpatients discharged from all replying hospitals. Obstetric patients were 18.4% of the reported discharges—somewhat higher than a previous estimate of around 17.5% (Bulletin 99 [6]), and the remaining 42.2% were, of course, inpatients in the "All other" category. The replying mental and tuberculosis hospitals as a group discharged only 271,762 of the nearly 16 million total reported discharges. When the estimates for the 382 nonreplying mental and tuberculosis hospitals were included, these discharges were only 417,549 inpatients out of the nearly 20,700,000 discharged during the year. Exclusion of these two types of hospitals made the percentages of inpatients discharged from the general and special hospitals only slightly different (40 for surgical, 18.6 for obstetric, and 41.4 for "All other") from the percentages for all the hospitals cited above. The percentages for the mental and tuberculosis hospitals treated as a group were, however, quite different; 86.8% of the discharges were in the "All other" category, while only 11.1% were classified as surgical; obstetric cases were 2.1% and would have been about 0.1% if the one tuberculosis hospital (with many nontuberculous inpatients) had not been included.

While the term "surgical cases" was not defined rigorously enough to permit detailed analysis of such discharges, it may be significant that four-fifths of all reported surgical patients discharged were from the nongovernmental general and special hospitals. Of the obstetric discharges, 99.8% were from general and special hospitals. In fact, all but 156 of the reported obstetric discharges would have been included in this group if one hospital with large maternity and isolation sections had not been coded as a tuberculosis hospital. Even though most of the discharges from mental and tuberculosis hospitals were in the "All other" category, they were only 3.5% of all discharges in the "All other" category. These percentages are derived from the data given in table 3; complete percentage distributions appear in the appendix.

As shown in table 2, the total inpatients discharged from mental and tuberculosis hospitals constituted only 1.7% of all reported (15,810,084) inpatients discharged for the year. Most of the remaining comments are, therefore, concerned with the 98.3% of the inpatients discharged from the general and special hospitals.

Table 4 shows the percentage distribution by categories of all reported inpatients discharged by the general and special hospitals classified according to type of control. The percentages in column (1)—for all replying general and special hospitals—vary considerably from the percentages in the same row in the other columns. For example, although 40% of the reported inpatients discharged from all general and special hospitals were surgical discharges [col. (1)] the range was 27.4% from military hospitals to 42.5% from nongovernmental hospitals. The percentage distribution for obstetric discharges is almost incredible—18.6% for all hospitals, with a high of 19.5% from federal military hospitals (108,584 out of 557,033 inpatients discharged). Bearing in mind the fact that our general objective in this five-year study is to measure the totality of physician services, we feel constrained to ask a sharp question: Why should physicians have a larger proportion of obstetric patients (discharged) in military hospitals than in nongovernmental or local governmental hospitals in the general and special class of hospitals?

Size of Hospital.—Appendix tables in Bulletin 102A show some rather interesting variations when the replying general and special hospitals are grouped according to size. The largest number of each of the three types (1*a*, 1*b*, and 1*c*) of discharges was from hospitals having 100 to 199 beds. The ratio of surgical discharges to all discharges was largest (44.3%) for hospitals in the bed-size class 300 to 499. Large general and special hospitals, those having 500 or more beds, accounted for the smallest proportion of obstetric cases, 16.5%; the proportion was highest, 19.5%, in hospitals having fewer than 25 beds. As noted in the appendix, the highest estimate for nonreplying hospitals was based on a classification of hospitals by size.

Hospital by Region.—Other appendix tables reveal that the largest number of each group of discharges was made from hospitals in the east north central region. As might be expected from the regional birth rates, the ratio of obstetric cases to all discharges was also highest (20.1%) for the east north central region and lowest (17.5%) for hospitals in New England. Estimates for the nonreplying hospitals, when made by region, did not vary by more than a few thousand from those made on the basis of type of control.

Cardiac and Neoplastic Disease and Fractures

It is important to emphasize the fact that the data presented in the survey do not account for all patients with a diagnosis of cardiac or neoplastic disease or fractures who were treated by physicians in hospitals in 1954. Undoubtedly there were large numbers of discharged inpatients with each of these conditions as secondary diagnoses. Because primary diagnoses were called for, the cardiac and neoplastic diseases and fractures were not among the primary diagnoses reported by the mental and tuberculosis hospitals. Moreover, since every general and special hospital in the survey did not answer all three parts of question 2, percentages of all discharges are based upon the discharges reported by the hospitals that did reply to the particular item, including those that reported "none." (Replies for each subcategory of replying hospitals, together with the estimated total for all hospitals, are shown in the appendix tables.)

As table 3 shows, the 2,909 replying general and special hospitals reported 627,168 inpatients having a primary diagnosis of cardiac disease discharged during the calendar year 1954. It is estimated that the nonreplying 3,072 general and special hospitals, which had only 37% of the admissions, discharged an additional 362,484 such patients during the same period, bringing the estimated total for all 5,981 general and special hospitals to 989,652. This is rounded to 1 million on the chart. Discharged inpatients with a primary diagnosis of cardiac disease were 4.9% of the number discharged from general and special hospitals. Interestingly enough, the highest percentage, 11.7, was from Veterans Administration hospitals; the percentage for local governmental hospitals was also higher than for the total (see table 4).

The 2,961 hospitals that answered the question on inpatients discharged with a primary diagnosis of malignant neoplastic disease reported 396,320 such patients. It is estimated that the 3,020 nonreplying hospitals discharged 205,296 such patients, bringing the total for all general and special hospitals to 601,616. This is reduced to 585,000 on the chart because of the lower estimate (571,000) based on admissions by size.

Table 4.—*Percentage Distribution by Eight Categories of Reported Inpatients Discharged from General and Special Hospitals, According to Hospital Type of Control, 1954*

Diagnostic Category of Discharged Inpatients	All (1)	Non governmental (2)	Local Government (3)	State Government (4)	Federal Government Total (5)	Federal Government Military (6)	Federal Government V. A. (7)	Federal Government Other (8)
1 a Surgical	40.0	42.5	31.0	37.7	32.0	27.4	39.3	33.1
b. Obstetric	18.6	19.1	19.3	18.2	11.9	19.5	0.0	10.2
c "All others"	41.4	38.4	49.7	44.1	56.1	53.1	60.7	56.7
d Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0
2 a Cardiac	4.9	4.7	5.7	4.9	5.5	1.9	11.7	5.2
b. Malignant neoplasm	3.0	2.9	2.8	6.5	2.9	1.1	6.1	2.4
c. Fracture	3.6	3.4	4.2	3.3	4.0	4.1	4.0	3.4
3 a Tonsillectomy	5.5	6.3	3.6	1.9	1.7	2.2	0.9	2.1
b. Appendectomy	2.4	2.6	2.1	1.4	1.3	1.4	1.0	1.1

Inpatients discharged with a primary diagnosis of malignant neoplastic disease were 3% of the total discharges from replying hospitals. The highest such percentage, 6.5, was for the discharges from state hospitals. As with cardiac disease, the percentage was also high, 6.1, for the Veterans Administration hospitals.

The 3,227 general and special hospitals that answered question 2c reported that 501,629 of the inpatients discharged in 1954 had a primary diagnosis of fracture. It is estimated that the corresponding number for the nonreplying hospitals was 219,662, thereby bringing to 721,291 the 1954 total for all general and special hospitals. This estimate was rounded to 720,000 on the chart. Patients with fractures were 3.6% of the discharges from all replying hospitals and 4.2% of the discharges from local governmental hospitals.

Size of Hospital.—Estimates made when the replies were grouped by size of hospital (see appendix tables) gave 979,374 as the total of cardiac cases—or only about 10,000 fewer than the estimate obtained for the type-of-control classification. The percentage (of total discharges) for the replying hospitals ranged from 4 for hospitals having 25 to 49 beds to 5.8 for hospitals having 500 or more beds. The estimated totals were 30,000 fewer for malignant neoplastic disease and 3,000 more for fractures when computations were based on size classifications of hospitals.

Hospital by Region.—When estimates were based on hospitals grouped according to their regional location, shown on appendix tables, the estimated totals for the nonreplying hospitals for cardiac disease and malignant neoplastic disease fell midway between the estimates based on type of control and bed size. The highest cardiac ratio was 5.5% for the Pacific region, and the lowest was 4.1% for the east south central and mountain regions. The malignant neoplastic disease ratio was highest, 3.4%, for the middle Atlantic region and lowest, 2.3%, for the mountain region. The ratios for fractures varied little from the average of 3.6%, with the possible exception of the Pacific region, where it was 3.9%.

Tonsillectomies and Appendectomies

Approximately 94% of the replying hospitals (slightly less than 4,100) answered question 3. There is no reason to believe that, for the general and special hospitals, the results would have been different had operations performed on "discharged inpatients" rather than on "inpatients" been requested. For the mental and tuberculosis hospitals, however, it may be that a few of the tonsillectomies and/or appendectomies were performed on persons who were still inpatients at the end of 1954. However, since the tonsillectomies and appendectomies reported by the mental and tuberculosis hospitals are only 0.1% and 0.2% of the total numbers of these operations (see appendix table), there is little reason for not continuing to use "discharged inpatients" as the base for the computation of ratios.

As shown in table 3, 813,139 tonsillectomies were performed on inpatients in 4,088 replying hospitals; 812,244 or 99.9% of these were in general and special hospitals, with only 895 in mental and tuberculosis hospitals. Our estimate of 288,326 such operations for the 2,882 nonreplying hospitals raises the total number to 1,101,465 (rounded to 1,100,000 on the chart). The ratios were 5.4% for all hospitals, 5.5% for general and special hospitals, and 0.3% for the mental and tuberculosis hospitals. Considering only the general and special hospitals (table 4), the highest ratio of tonsillectomies performed on inpatients was 6.3% for the nongovernmental hospitals; the lowest such ratio was 0.9% for the Veterans Administration hospitals. Indeed, for all of the seven breakdowns according to type of control the ratios were markedly different from the average ratio of 5.5%.

The same hospitals reported 358,148 appendectomies, only 0.2% (832) of which were performed in mental and tuberculosis hospitals. It is estimated that an additional 127,814 appendectomies were performed in the 2,882 nonreplying hospitals and that the total number of these operations in 6,970 hospitals accepted for listing in 1954 was 485,962 (raised and rounded to 500,000 on the chart). The ratios were 2.4% for all hospitals, 2.4% for general and special hospitals, and 0.3% for mental and tuberculosis hospitals (table 3). The appendectomy ratios for the seven different types of general and special hospitals ranged from 2.6% for the nongovernmental hospitals to 1% for the Veterans Administration hospitals. In state general and special hospitals the ratios for these two operations were, of course, much lower than the corresponding ratios for all hospitals—a sharp contrast to the higher ratio for malignant neoplastic disease. More than 80% of both of these operations were, however, performed in nongovernmental hospitals, with city and county controlled hospitals accounting for most of the remainders.

Size of Hospital.—Appendix tables reveal that about 30% of the tonsillectomies and appendectomies were performed in hospitals having 100 to 199 beds, while about 10% of these operations were performed in hospitals with 50 or fewer beds. The largest hospitals, those having 500 or more beds, discharged only about 6% and 8% of the tonsillectomy and appendectomy patients respectively. The smallest hospitals, those having fewer than 25 beds, discharged relatively more tonsillectomy (7.8%) and appendectomy (3.6%) patients out of their total discharges than any other class. More generally, these ratios were lower for hospitals with more beds—both for all hospitals and for general and special hospitals. In the mental and tuberculosis hospitals (see appendix tables), approximately three-fourths of these operations were performed in the largest hospitals, and it was only for the Veterans Administration mental and tuberculosis hospitals that the ratios approach 1%. When estimates were prepared for nonreplying hospitals according to seven size classifications, the total number of tonsillectomies was raised by only 34,000 and the number of appendectomies by only 18,000.

Hospitals by Region.—Since the east north central region had the greatest number of replying hospitals and the greatest number of admissions and discharges, it is consistent that the largest number of tonsillectomies and appendectomies was reported by this region (see appendix tables). The ratio of tonsillectomies to discharges was highest for New England (6.3%) and lowest for the east south central region (4.1%). The ratios of appendectomies to discharges varied little from the average of 2.4% of all regions (see appendix tables).

Summary

Of the discharged inpatients treated in hospitals by physicians in calendar year 1954, 18.4% were classified as obstetric. These totaled approximately 3,800,000—about 500,000 more than the number of births in hospitals reported by the A. H. A. for the 12-month period ending Sept. 30, 1954. Physicians performed one or more surgical procedures on 39.4%, or about 8,100,000, of their hospitalized patients in the calendar year 1954. Among these procedures were about 1,100,000 tonsillectomies and about 500,000 appendectomies. Hospitalized patients who had these two operations performed by their physicians were 5.4% and 2.4%, respectively, of the total inpatients discharged during the year. For the discharged patients from only nongovernmental general and special hospitals, these ratios were 6.3% for tonsillectomies and 2.6% for appendectomies.

In addition to the broad classifications of "obstetric inpatients discharged" and "inpatients discharged upon whom one or more surgical procedures were performed," there were about 8,800,000 "All other" inpatients discharged during the calendar year 1954. These included patients being treated in hospitals for a great variety of conditions; it also included some well persons who were briefly hospitalized by their physician for "physical check-ups" by the total medical care team.

With all types of general and special hospitals (from which 98.3% of all inpatients were discharged) considered, an estimated 4.9%—or about 1 million inpatients—had a primary diagnosis of some form of cardiac disease. About 585,000 of the total inpatients, discharged from these hospitals in 1954 had a primary diagnosis of some form of malignant neoplastic disease; this was 3% of the number discharged. About 720,000 of these discharged inpatients, or 3.6% of the total, were discharged with a primary diagnosis of fracture. These three diagnostic categories are mutually exclusive of one another, and they accounted for a total of 11.5% of all inpatients discharged from Veterans Administration hospitals. Malignant neoplastic disease accounted for 6.5% of the discharges from state hospitals and fractures for 4.2% of those from local governmental hospitals.

Since it is probable that most, if not all, of the fracture cases were also accident cases, one interesting result of this survey is that at least 22% of the patients treated by physicians in hospitals in 1954 and discharged therefrom did not have diseases but were hospitalized for conditions related to pregnancy (18.4%) or to accidents (3.6%). Moreover, because accidents can and do result in many more diagnostic conditions than "fractures," it is likely that the true percentage of patients treated in hospitals by physicians for conditions due to disease will be found to be less than 78%.

MEDICAL NEWS

CALIFORNIA

Heart Association Moves.—The Los Angeles County Heart Association has moved to new headquarters at 660 S. Western Ave., Los Angeles 5, in the Franklin Life Building (telephone, DUnkirk 5-4231). This move effects a consolidation of the administrative and program offices, formerly located at 316 S. Bonnie Brae St., and the heart fund headquarters, formerly located at 5501 Wilshire Blvd.

New Orthopedic Hospital.—Plans have been approved for the construction of a $3,780,000 hospital to be built on the present site of the Orthopaedic Hospital at 24th and Flower streets in Los Angeles. The six-story structure, which will replace the 42-year-old main building, will provide 128 bed spaces, remodeled outpatient clinics, and four surgical rooms. The building will increase bed capacity by 50. The hospital will also enlarge its research and training program.

Dr. Kempe Goes to Colorado.—Dr. C. Henry Kempe, formerly assistant professor of pediatrics, University of California School of Medicine, San Francisco, has been named head of the department of pediatrics at the University of Colorado School of Medicine in Denver, succeeding Dr. Robert H. Alway, who resigned in 1955 to join Stanford University School of Medicine, Stanford University—San Francisco. Dr. Kempe was scheduled to arrive in Denver about Nov. 1. In 1955 Dr. Kempe was on leave to the Rockefeller Virus Laboratory in Rome on a Fulbright research grant. He has also carried out virus research in India and Indochina.

ILLINOIS

Chicago

Dr. Lawless Honored.—Kupat Holim, the medical department of the Israeli Federation of Labor, will establish a 35-bed T. K. Lawless Dermatology Department as a part of the Beilinson Hospital in Israel, an institution of 700 beds, where medical students of Jerusalem University take their clinical training. The dermatology department will cost $440,500, of which $160,500 will be raised in the United States by friends of Dr. Lawless of Chicago. Kupat Holim has constructed a system of 14 hospitals similar to those recently completed in the United States by the United Mine Workers. The new T. K. Lawless Dermatology Department will serve as a consultation and research center for all Kupat Holim institutions in Israel. Kupat Holim honored Dr. Lawless "in recognition of his stalwart accomplishments as a medical practitioner and teacher. In acknowledgement of his broad humanitarianism which transcends the boundaries of race and creed. In appreciation of his generous support of the State of Israel and its people."

KANSAS

Jordan Memorial Fund.—Friends of Dr. Ralph E. Jordan, Emporia, who died of bulbar poliomyelitis on July 10, have initiated a memorial fund to be used for the education of his six children. Anyone wishing to contribute may send a check to Mr. Ivan Anderson, Administrator, Newman Hospital, Emporia.

KENTUCKY

Personal.—The University of Louisville School of Medicine announces the appointment of Dr. Malcolm D. Thompson as professor of surgery and Dr. DeLou P. Hall as associate professor of surgery.——Dr. Robert D. Collins, currently on active duty at the Army Research Laboratory, Fort Knox, has been awarded a senior research fellowship by the U. S. Public Health Service. Following his release from the service, Dr. Collins will spend two years studying basic processes in the inflammatory reaction, after which he will return to the department of pathology, Vanderbilt University School of Medicine, Nashville, Tenn., as an assistant professor.

LOUISIANA

Tulane Promotions.—Tulane University School of Medicine, New Orleans, announces recent faculty promotions. Promoted to the rank of associate professor are Dr. Gustav C. Bahn, opthalmology; Dr. Joseph V. Hopkins, clinical medicine; Drs. Robert H. Lennox and Christopher H. Snyder, pediatrics; and Drs. John W. S. Hunt, William J. Mogabgab, John C. S. Paterson, and Walter G. Unglaub, medicine. Newly appointed assistant professors are Dr. Charles C. Abbott, surgery; Dr. Ralph W. Buddington Jr., clinical psychiatry; Dr. Cornelia A. Eddy, microbiology; Dr. David J. Farwell, otolaryngology; Dr. Henry M. Gelfand, epidemiology; Dr. Martin Goldfield, medicine; Drs. Francis M. Harris Jr., Stephen L. Madey, and Emma L. Sailors, pediatrics; Richard G. Hibbs, Ph.D., anatomy; Dr. Ruth D. Paterson, neurology and medicine; Dr. Neill K. Weaver, clinical medicine and public health; and Robert G. Yaeger, Ph.D., medicine and tropical medicine and public health.

Laboratory for Metabolic Research.—The Urban Maes Laboratory for endocrine and metabolic research was recently established in New Orleans under the auspices of the Urban Maes Research Foundation and the joint sponsorship of the Louisiana State University and Tulane University schools of medicine and Touro Infirmary, New Orleans. Temporary facilities will be established at the Louisiana State University School of Medicine until a permanent laboratory is constructed at Touro Infirmary. Dr. Floyd R. Skelton, former assistant professor of pathology at the Medical College of Georgia, Augusta, and now associate professor of pathology at Louisiana State University School of Medicine, is director of the laboratory. Funds to equip and operate the laboratory will come from public subscriptions, the research foundation, grants from federal agencies, and other sources. Dr. Hans Selye, director of the Institute of Experimental Medicine and Surgery, University of Montreal, Canada, was the principal speaker at the dedication ceremonies.

MASSACHUSETTS

Dr. Martha Eliot Goes to Harvard.—Dr. Martha M. Eliot, chief, U. S. Children's Bureau in Washington, D. C., has been appointed professor and head of the department of maternal and child health at Harvard University School of Public Health, Boston. On Jan. 1, 1957, she will succeed Dr. Harold C. Stuart, who helped to found the department in 1927 and who asks to be relieved of administrative duties and direction of the department's teaching program so that he may devote most of his time to research. Dr. Stuart will continue as a member of the department staff and will concentrate on the completion of a child growth and development study for which he and colleagues have been accumulating data since 1930. Dr. Eliot has directed the activities of the children's bureau in the U. S. Department of Health, Education, and Welfare since 1951. She is currently the U. S. representative on the board of the United Nations' International Children's Emergency Fund. She is a past-president of the American Public Health Association (1947-1948) and the National Conference of Social Work (1949).

Personal.—Dr. Hans Waine, Newton, has been appointed chief of staff of the Boston dispensary, a unit of the New England Medical Center, Boston. The office of chief of staff is a new medical appointment in the development and expansion program of the dispensary, which is constructing a million-dollar rehabilitation institute. Dr. Waine will work with Tufts College Medical School, Boston, and the other New England Medical Center units.——Dr. William A. McCausland, Norwell, has been appointed medical director of Hood Rubber Company, a division of the B. F. Goodrich Company, Watertown.——Dr. Laurence L. Robbins, chief, department of radiology, Massachusetts

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

General Hospital, Boston, was recently chosen the George Winslow Holmes Lecturer for 1956. His topic was "The Radiologist Faces Automation." After the lecture before the annual meeting of the New England Roentgen Ray Society, a silver Paul Revere pitcher was presented to him.—Dr. Joseph W. Gardella, research associate in medicine, Harvard Medical School, has been named assistant dean for student affairs in the faculty of medicine, Harvard University, succeeding Dr. William F. Ketchum, who plans to return to private practice. At Harvard College, Dr. Gardella was captain of the varsity football team in 1940.

MINNESOTA

Dr. Huenekens Honored.—Dr. Edgar J. Huenekens was honored for his long service to pediatrics and to the community at a recent banquet in Minneapolis, sponsored by members of the Minneapolis Pediatric Society, most of whom received their professional training under Dr. Huenekens. A library fund, bearing Dr. Huenekens' name, has been established for the future Children's Hospital in Minneapolis.

Gray Memorial Fund.—The Howard K. Gray Memorial Fund, in memory of Dr. Gray, head of a section of surgery at the Mayo Clinic from 1935 until his death, Sept. 6, 1955, will provide grants to fellows or former fellows of the Mayo Foundation for travel and other expenses incidental to visits to leading surgical centers in the United States and Canada. The recipients will be nominated by a committee consisting of the director of the Mayo Foundation, the chairman of the Surgical Society of the Mayo Clinic, all surgeons who serve as members of the board of governors of the Mayo Clinic, and such other persons as may be selected. Contributions thus far are sufficient to assure a return income that will allow the recipient to spend at least two weeks at some American surgical center.

Blood Bank Dedicated.—The $400,000 Minneapolis War Memorial Blood Bank was dedicated on Nov. 11 at 2303 Park Ave., South, with Dr. Leroy E. Burney, surgeon general, U. S. Public Health Service, Washington, D. C., as guest speaker. The bank will collect blood for the use of all hospitals in the community and will provide (1) a central depository where various groups can deposit their blood to their credit and have it available when needed at any point in the city; (2) a community-controlled reserve of plasma adequate for ordinary disasters; (3) a technical laboratory team to assist in transfusion problems, to study transfusion reactions, and to contribute to transfusion safety; and (4) a completely equipped laboratory in which to carry out studies of Rh and other hereditary antigens in blood. G. Albin Matson, Ph.D., is director of the bank.

MISSOURI

Personal.—Dr. Walter J. Burdette was recently appointed professor of clinical surgery at the St. Louis University School of Medicine, director of the St. Louis University surgical service at Veterans Hospital, and cancer coordinator for the school of medicine.

Hospital News.—The Jewish Sanatorium has moved from Fee Fee Road, Robertson, to new quarters at the Jewish Hospital medical center, 216 Kingshighway Blvd., St. Louis, where the sanatorium patients will be cared for in the 68-bed chronic disease division of the Mark C. Steinberg Memorial Hospital. The move is part of a larger project integrating the facilities and program at the sanatorium, the Miriam Rosa Bry Convalescent-Rehabilitation Hospital, Webster Groves, and the Jewish Medical Social Service Bureau into one large medical center at the Jewish Hospital of St. Louis.

NEW YORK

Premature Baby Care.—The New York State Department of Health has approved Samaritan Hospital in Troy as a center for premature baby care. Parents of premature infants born in Samaritan Hospital may receive financial assistance from the state and county if the extended care necessary for premature infants represents a financial problem. Parents of such premature infants may apply to the Rensselaer County Health Department for the financial assistance, which must be authorized by the Rensselaer County Children's Court.

Dr. Taylor's Centennial.—Dr. J. Richard Taylor, Brooklyn, descendant of President Zachary Taylor, celebrated his 100th birthday, Nov. 22. Dr. Taylor served in the Spanish-American War, was surgeon in charge of the Johnstown Flood emergency operation, and was influential in the opening of the Northwest Territory. Now a resident of the Buckminster Nursing Home, 630 Ocean Ave., he is said to be the oldest living graduate of the University of Pennsylvania School of Medicine, Philadelphia.

Faculty Promotions.—The State University of New York College of Medicine in Syracuse announces the following promotions:

Department of radiology: Dr. Paul A. Riemenschneider, full professor; Dr. Alfred S. Berne, associate professor; and Dr. Alfred Schick, assistant professor.

Department of surgery: Dr. Lloyd S. Rogers, associate professor; and Drs. William L. Parry, George A. Sisson, Bernard S. Piskor, Donald F. Buschle, Paul M. Cramer, Jacob S. Israel, Clifford J. Straehley Jr., and Frederick E. Wetherell, clinical assistant professors.

Department of medicine: Drs. Max Kutzer and Paul C. Clark, clinical professors; Drs. Robert E. Westlake and William A. Schiess, clinical associate professors; and Drs. George R. Burnett, Benjamin F. Levy, Murray A. Grossman, Irving Swartz, and Armand U. Aquilino, clinical assistant professors.

Department of otolaryngology: Drs. David W. Brewer, Lee R. Stoner Jr., and Richard L. Sullivan, clinical associate professors; Drs. David L. Poushter and Wesley H. Bradley, clinical assistant professors; and Dr. George G. Lerner, assistant professor.

Department of obstetrics: Dr. Albert W. Van Ness, clinical professor; and Dr. James N. Capps, clinical assistant professor.

New York City

Lecture on Neoplastic Diseases.—In its series of lectures on neoplastic diseases, Montefiore Hospital will offer "Carcinoma of the Ovary" by Dr. Howard C. Taylor Jr., professor of obstetrics and gynecology, Columbia University College of Physicians and Surgeons, Jan. 4, 1957, at 3 p. m., in the West Basement Conference Hall.

New Psychiatry Professor at Social Work School.—Dr. Maurice R. Friend, lecturer at the State University College of Medicine Psychoanalytic Institute, has been appointed the first professor of psychiatry to occupy the recently established Marion E. Kenworthy Chair in Psychiatry at the New York School of Social Work, Columbia University. The chair was created by a $400,000 endowment fund contributed by friends of Dr. Marion E. Kenworthy on her retirement as professor of psychiatry at the school. Dr. Friend will continue in private practice.

TENNESSEE

Personal.—Dr. Virgil S. LeQuire, assistant professor of anatomy, Vanderbilt University School of Medicine, Nashville, has been awarded a senior research fellowship by the U. S. Public Health Service. The title of his project is "Vascular Embolization."

WEST VIRGINIA

Camp for Handicapped Children.—According to the West Virginia State Medical Association, Galahad, the new camp for handicapped children, now under construction at Quick, 35 mi. northeast of Charleston, will be used next summer by diabetic and blind children of the state. A continuing statewide fund-raising campaign is in progress. Dr. Richard V. Lynch Jr., Clarksburg, and Drs. John H. Gile and Oliver H. Brundage, Parkersburg, are members of the planning committee.

Personal.—Dr. William S. Herold, Fayetteville, has been appointed health officer of Fayette County.—Dr. Guy R. Post, Parkersburg, director of the Wood County-Parkersburg Health Department, has been named a member of the Royal Society of Health of London.—Dr. Laurence L. Duncan, a native of Charleston, has been named assistant professor of pathology at West Virginia University School of Medicine, Morgantown. He interned at Henry Ford Hospital in Detroit and recently completed a residency in surgery at the Veterans Administration Hospital in Houston, Texas.—Dr. Helen B. Fraser, Charleston, director, division of maternal and child health, state department of health, since 1952, recently resigned to accept appointment as director, division of maternal and child health, Kentucky State Department of Health, with headquarters in Louisville.—Lieut. E. Lowell Berry, M. C., U. S. Naval Reserve, who has been on duty at the Boston Naval Shipyard dispensary for two years, has accepted appointment in Pittsburgh as chief, division of industrial health, Allegheny County Department of Health, and as lecturer in occupational medicine, University of Pittsburgh Graduate School of Public Health.

GENERAL

Seminar in Plastic and Reconstructive Surgery.—The American Otorhinologic Society for Plastic Surgery will hold a seminar in plastic and reconstructive surgery of the head and neck at the Louisiana State University School of Medicine, New Orleans, Feb. 17-23, 1957. Information may be obtained from Dr. Louis J. Feit, Secretary, 66 Park Ave., New York 16.

Award in Proctology.—The International Academy of Proctology announces its annual award contest for 1956-1957 in which the best unpublished contribution on proctology or allied subjects will be awarded $100 and a certificate of merit. Entries (limited to 5,000 words, typewritten in English, and submitted in five copies) should be submitted before Feb. 1, 1957, to the International Academy of Proctology, 147-41 Sanford Ave., Flushing, N. Y.

Oscar Hunter Memorial Award.—The American Therapeutic Society invites nominations for the Oscar Hunter Memorial award, presented annually in honor of its late secretary, Dr. Oscar B. Hunter. The award consists of a bronze medal struck in the likeness of Dr. Hunter and engraved with the name of the recipient. The winner is expected to present a paper at the time of the award. Travel expenses to the meeting will be furnished. Nominations for the 1957 award should be submitted before Feb. 1 to Dr. Harry E. Ungerleider, 393 Seventh Ave., New York 1.

Kraepelin Commemorative Meeting.—During the 123rd annual meeting of the American Association for the Advancement of Science, Dec. 26-31, in New York City, a symposium, "Epidemiology of Mental Disorders," will be presented under the co-sponsorship of the American Psychiatric Association and the American Public Health Association at the Sky Top, Hotel Statler. The program, which will commemorate the centennial of the birth of Emil Kraepelin, has been arranged by Dr. Benjamin Pasamanick, Ohio State University Health Center, Columbus. It will open at 9 a. m. Thursday with the memorial lecture by Dr. Eugen Kahn, Houston, Texas. In all, 12 presentations will be made.

Program of Engineering Section.—At the meeting of the American Association for the Advancement of Science, Statler Hotel, New York City, Dec. 26-27, the engineering section will present a program on "Aids for Environmental Control," which will open Wednesday, 9:30 a. m., with "Overcoming Normal and Abnormal Physical Limitations." Wednesday afternoon the session on "Extending Mental and Rational Powers" will be opened by Dr. Charles M. Gratz, New York City, whose subject will be "Biomechanics in Crash Mortality: The Surgical Approach Coordinating Man's Built-in Crash Defenses." The Thursday morning program will consist of four papers: "Translating Teletypesetter Tape to Braille," "Reduction of Speech Signals for Easier Transmission," "Mechanical Translation of German," and "Mechanical Translation of Russian."

Millions in Grants for Cancer Research.—The American Cancer Society, which recently reorganized its research program, announces that it can distribute at least 7 million dollars in 1957 to individual scientists and research institutions prepared to investigate problems pertinent to cancer control. Application forms may be obtained by writing to the American Cancer Society, 521 W. 57th St., New York 19. Applications received before Jan. 1 will be acted on during the late winter and early spring, and most grants will become effective July 1, 1957. Other deadlines for receipt of applications will be May 1 and Sept. 1. Types of grants include project grants, program grants, institutional research grants, contracts for research, postdoctoral fellowships, scholarships in cancer research, and additional faculty-level positions.

Course on Diseases of the Chest.—The sixth biennial postgraduate course on diseases of the chest, co-sponsored by the Los Angeles County Tuberculosis and Health Association and the Los Angeles County Medical Association, will be given Jan. 31–Feb. 2 in Los Angeles. Among many other things on the program will be a cancer workshop, with division of the class into small groups involving a panel composed of a surgeon, an internist, and a pathologist. An optional feature on Wednesday will be specially arranged observations of local hospital clinics, activities, and conferences. The faculty will include Drs. David T. Carr, Rochester, Minn.; Maurice S. Segal, Boston; Edgar W. Davis, Washington, D. C.; H. Corwin Hinshaw, San Francisco; and local chest specialists. The registration fee of $35 will include a banquet on Thursday evening. Information may be obtained by writing to Dr. David Salkin, 1670 Beverly Blvd., Los Angeles 26.

Fourth Fatal Case of Rabies.—According to the U. S. Public Health Service, S. Edward Sulkin, Ph.D., Southwestern Medical School of the University of Texas, Dallas, has reported a fatal case of human rabies, the fourth in the area during the current year. The victim was a 63-year-old man whose death followed an incubation period of 54 days. The California State Department of Public Health has reported a total of 264 cases of rabies in animals for the period Jan. 1–Oct. 9, 1956. Of these, 126 were in dogs, 101 in skunks, and 27 in cattle. The remainder were in various domestic and wild animals. Dr. Walton H. Y. Smith, Montgomery, Alabama State Department of Public Health, has reported the second case of bat rabies within one month. A bat with symptoms of rabies captured in Mobile County showed Negri bodies in its brain tissue. Rabies virus was isolated from both the brain and salivary glands at the Virus and Rickettsia Laboratory, U.S. Public Health Service, Montgomery. The bat was identified as an insectivorous species, *Lasiurus borealis borealis*.

Grant for Mental Health Study.—Dr. Jack R. Ewalt, director of the three-year national mental health study recently initiated by the Joint Commission on Mental Illness and Health (808 Memorial Dr., Cambridge, Mass.) has announced receipt of $25,000 from the Smith, Kline and French Foundation of Philadelphia for support of the commission's work. The purposes of the commission's study are to appraise mental health knowledge and methods and find new approaches to combating mental illness or better ways of implementing existing methods. The study was undertaken under a 1955 Act of Congress authorizing the National Institute of Mental Health to grant $1,250,000 and providing for acceptance by the commission of additional support from nongovernmental sources. The Smith, Kline and French grant is the first received from private foundations or industrial sources as a supplement to the government funds. Dr. Kenneth E. Appel of Philadelphia is president of the Joint Commission on Mental Illness and Health and Dr. Leo H. Bartemeier of Baltimore is chairman of its board of trustees.

Continental Casualty Research Grants.—The Continental Casualty Company has established grants in support of promising research in student medicine to encourage investigation that will promote the health of college students and benefit student medical practices. Two grants of $500 will be made annually, one to support research in a college of less than 2,000 enrollment, the other in a college of more than 2,000 enrollment. Grants can be used for either clinical or experimental research (1) as the sole source of support for exploratory or small-scale studies or (2) in conjunction with college or other funds to support sections of a large-scale research project. Grant recipients will be selected by the committee on research of the American College Health Association. Member colleges are invited to submit research proposals (six copies) at any time. Recipients, to be announced at the annual meeting of the association, will be based on all proposals received by Feb. 1 of that year. Proposals may be mailed to John Summerskill, Ph.D., Chairman, Committee on Research, Student Medical Clinic, Cornell University, Ithaca, N. Y.

Research Centers in Higher Education.—The Carnegie Corporation of New York, 589 Fifth Ave., New York 17, has issued a list of grants totaling almost 2 million dollars and providing for

General Hospital, Boston, was recently chosen the George Winslow Holmes Lecturer for 1956. His topic was "The Radiologist Faces Automation." After the lecture before the annual meeting of the New England Roentgen Ray Society, a silver Paul Revere pitcher was presented to him.—Dr. Joseph W. Gardella, research associate in medicine, Harvard Medical School, has been named assistant dean for student affairs in the faculty of medicine, Harvard University, succeeding Dr. William F. Ketchum, who plans to return to private practice. At Harvard College, Dr. Gardella was captain of the varsity football team in 1940.

MINNESOTA

Dr. Huenekens Honored.—Dr. Edgar J. Huenekens was honored for his long service to pediatrics and to the community at a recent banquet in Minneapolis, sponsored by members of the Minneapolis Pediatric Society, most of whom received their professional training under Dr. Huenekens. A library fund, bearing Dr. Huenekens' name, has been established for the future Children's Hospital in Minneapolis.

Gray Memorial Fund.—The Howard K. Gray Memorial Fund, in memory of Dr. Gray, head of a section of surgery at the Mayo Clinic from 1935 until his death, Sept. 6, 1955, will provide grants to fellows or former fellows of the Mayo Foundation for travel and other expenses incidental to visits to leading surgical centers in the United States and Canada. The recipients will be nominated by a committee consisting of the director of the Mayo Foundation, the chairman of the Surgical Society of the Mayo Clinic, all surgeons who serve as members of the board of governors of the Mayo Clinic, and such other persons as may be selected. Contributions thus far are sufficient to assure a return income that will allow the recipient to spend at least two weeks at some American surgical center.

Blood Bank Dedicated.—The $400,000 Minneapolis War Memorial Blood Bank was dedicated on Nov. 11 at 2303 Park Ave., South, with Dr. Leroy E. Burney, surgeon general, U. S. Public Health Service, Washington, D. C., as guest speaker. The bank will collect blood for the use of all hospitals in the community and will provide (1) a central depository where various groups can deposit their blood to their credit and have it available when needed at any point in the city; (2) a community-controlled reserve of plasma adequate for ordinary disasters; (3) a technical laboratory team to assist in transfusion problems, to study transfusion reactions, and to contribute to transfusion safety; and (4) a completely equipped laboratory in which to carry out studies of Rh and other hereditary antigens in blood. G. Albin Matson, Ph.D., is director of the bank.

MISSOURI

Personal.—Dr. Walter J. Burdette was recently appointed professor of clinical surgery at the St. Louis University School of Medicine, director of the St. Louis University surgical service at Veterans Hospital, and cancer coordinator for the school of medicine.

Hospital News.—The Jewish Sanatorium has moved from Fee Fee Road, Robertson, to new quarters at the Jewish Hospital medical center, 216 Kingshighway Blvd., St. Louis, where the sanatorium patients will be cared for in the 68-bed chronic disease division of the Mark C. Steinberg Memorial Hospital. The move is part of a larger project integrating the facilities and program at the sanatorium, the Miriam Rosa Bry Convalescent-Rehabilitation Hospital, Webster Groves, and the Jewish Medical Social Service Bureau into one large medical center at the Jewish Hospital of St. Louis.

NEW YORK

Premature Baby Care.—The New York State Department of Health has approved Samaritan Hospital in Troy as a center for premature baby care. Parents of premature infants born in Samaritan Hospital may receive financial assistance from the state and county if the extended care necessary for premature infants represents a financial problem. Parents of such premature infants may apply to the Rensselaer County Health Department for the financial assistance, which must be authorized by the Rensselaer County Children's Court.

Dr. Taylor's Centennial.—Dr. J. Richard Taylor, Brooklyn, descendant of President Zachary Taylor, celebrated his 100th birthday, Nov. 22. Dr. Taylor served in the Spanish-American War, was surgeon in charge of the Johnstown Flood emergency operation, and was influential in the opening of the Northwest Territory. Now a resident of the Buckminster Nursing Home, 630 Ocean Ave., he is said to be the oldest living graduate of the University of Pennsylvania School of Medicine, Philadelphia.

Faculty Promotions.—The State University of New York College of Medicine in Syracuse announces the following promotions:

Department of radiology: Dr. Paul A. Riemenschneider, full professor; Dr. Alfred S. Berne, associate professor; and Dr. Alfred Schick, assistant professor.

Department of surgery: Dr. Lloyd S. Rogers, associate professor; and Drs. William L. Parry, George A. Sisson, Bernard S. Piskor, Donald F. Buschle, Paul M. Cramer, Jacob S. Israel, Clifford J. Straehley Jr., and Frederick E. Wetherell, clinical assistant professors.

Department of medicine: Drs. Max Kutzer and Paul C. Clark, clinical professors; Drs. Robert E. Westlake and William A. Schiess, clinical associate professors; and Drs. George R. Burnett, Benjamin F. Levy, Murray A. Grossman, Irving Swartz, and Armand U. Aquilino, clinical assistant professors.

Department of otolaryngology: Drs. David W. Brewer, Lee R. Stoner Jr., and Richard L. Sullivan, clinical associate professors; Drs. David L. Poushter and Wesley H. Bradley, clinical assistant professors; and Dr. George C. Lerner, assistant professor.

Department of obstetrics: Dr. Albert W. Van Ness, clinical professor; and Dr. James N. Capps, clinical assistant professor.

New York City

Lecture on Neoplastic Diseases.—In its series of lectures on neoplastic diseases, Montefiore Hospital will offer "Carcinoma of the Ovary" by Dr. Howard C. Taylor Jr., professor of obstetrics and gynecology, Columbia University College of Physicians and Surgeons, Jan. 4, 1957, at 3 p. m., in the West Basement Conference Hall.

New Psychiatry Professor at Social Work School.—Dr. Maurice R. Friend, lecturer at the State University College of Medicine Psychoanalytic Institute, has been appointed the first professor of psychiatry to occupy the recently established Marion E. Kenworthy Chair in Psychiatry at the New York School of Social Work, Columbia University. The chair was created by a $400,000 endowment fund contributed by friends of Dr. Marion E. Kenworthy on her retirement as professor of psychiatry at the school. Dr. Friend will continue in private practice.

TENNESSEE

Personal.—Dr. Virgil S. LeQuire, assistant professor of anatomy, Vanderbilt University School of Medicine, Nashville, has been awarded a senior research fellowship by the U. S. Public Health Service. The title of his project is "Vascular Embolization."

WEST VIRGINIA

Camp for Handicapped Children.—According to the West Virginia State Medical Association, Galahad, the new camp for handicapped children, now under construction at Quick, 35 mi northeast of Charleston, will be used next summer by diabetic and blind children of the state. A continuing statewide fund-raising campaign is in progress. Dr. Richard V. Lynch Jr., Clarksburg, and Drs. John H. Gile and Oliver H. Brundage, Parkersburg, are members of the planning committee.

Personal.—Dr. William S. Herold, Fayetteville, has been appointed health officer of Fayette County.—Dr. Guy R. Post, Parkersburg, director of the Wood County-Parkersburg Health Department, has been named a member of the Royal Society of Health of London.—Dr. Laurence L. Duncan, a native of Charleston, has been named assistant professor of pathology at West Virginia University School of Medicine, Morgantown. He interned at Henry Ford Hospital in Detroit and recently completed a residency in surgery at the Veterans Administration Hospital in Houston, Texas.—Dr. Helen B. Fraser, Charleston, director, division of maternal and child health, state department of health, since 1952, recently resigned to accept appointment as director, division of maternal and child health, Kentucky State Department of Health, with headquarters in Louisville.—Lieut. E. Lowell Berry, M. C., U. S. Naval Reserve, who has

DEATHS

Lyman, David Russell ⊕ Wallingford, Conn.; born in Buffalo, N. Y., March 8, 1876; University of Virginia Department of Medicine, Charlottesville, 1899; past-president of the New Haven County Medical Society, Connecticut State Medical Society, American Sanatorium Association, Connecticut Tuberculosis Association, and American Climatological and Clinical Association; a founder and past-president of the National Tuberculosis Association, which in 1943 awarded him the Trudeau medal; member of the American Trudeau Society; during World War I served with the American Red Cross in France and was a member of the commission for the prevention of tuberculosis in France; an associate fellow of Branford College of Yale University, New Haven; a member of the council of the Henry Phipps Institute of the University of Pennsylvania in Philadelphia; held honorary degrees from Yale University, New Haven, and Wesleyan University, Middletown; a director of the First National Bank; for many years superintendent of the Gaylord Farm Sanatorium, where since 1953 was superintendent emeritus; died in the Grace-New Haven Community Hospital, New Haven, Oct. 15, aged 80, of leukemia.

Aubrey, John Forsyth, Miami, Fla.; born in Lynchburg, Va., Nov. 25, 1883; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1921; an associate member of the American Medical Association; member of the Medical and Chirurgical Faculty of Maryland; for many years practiced in Baltimore, where he was physician on the board of education; for 17 years surgeon of the Maryland State Penitentiary in Baltimore; medical officer with the 29th division, National Guard, during World War II and served as depot surgeon of the Philadelphia Signal Depot; retired as a colonel in 1946 after 23 years in the Army Reserve; veteran of World War I; died in the Mount Alto Veterans Administration Hospital, Washington, D. C., Oct. 4, aged 72, of paralysis agitans and cerebral atrophy.

Stephens, Philip Howard, Chino, Calif.; Washington University School of Medicine, St. Louis, 1899; formerly on the faculty of the College of Medical Evangelists, Loma Linda and Los Angeles; an associate member of the American Medical Association; member of the American Association for the Surgery of Trauma and the Industrial Medical Association; fellow of the American College of Surgeons; past-president of the Los Angeles County Medical Society; on the staffs of the Hospital of the Good Samaritan, Presbyterian Hospital-Olmsted Memorial, and the Cedars of Lebanon Hospital in Los Angeles; served as chief surgeon of the Union Pacific Railroad and medical director of the Southern California Bell Telephone Company; died in the Hospital of the Good Samaritan, Los Angeles, Sept. 8, aged 80.

Boyes, Truman Leo ⊕ New York City; born in Mount Hope, Ontario, Canada, 1898; University of Toronto Faculty of Medicine, Toronto, Canada, 1922; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; fellow of the American College of Surgeons; clinical professor of ophthalmology at the New York University Post-Graduate Medical School; formerly on the faculty of the New York University-Bellevue Medical Center; on the staffs of the St. Mary's Hospital in Hoboken, N. J., New York Eye and Ear Infirmary, Misericordia Hospital, and the Manhattan Eye, Ear and Throat Hospital; died in the Doctors Hospital Oct. 17, aged 58, of a heart attack.

McCamant, Thomas Jefferson ⊕ El Paso, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, Fort Worth, 1902; past-president of the El Paso County Medical Society; served as president of the Texas Public Health Association; veteran of the Spanish-American War and World War I; during World War II served as chairman of procurement and assignment of physicians for the Armed Forces; formerly city and county health officer; in 1935 a three county health unit, comprising El Paso, Hudspeth, and Culbertson counties, was established under his supervision; on the staffs of the Southwestern General Hospital and the Hotel Dieu, Sisters' Hospital; died Sept. 2, aged 82, of coronary occlusion.

Gervin, Peter Alphonse, San Diego, Calif.; born in Athol, Mass., Aug. 20, 1920; Tufts College Medical School, Boston, 1946; certified by the National Board of Medical Examiners; interned at the U. S. Naval Hospital in Corona; formerly a resident at the City Memorial Hospital in Winston-Salem, N. C., and the San Diego County General Hospital; served in the U. S. Naval Reserve; on the staffs of the Mercy Hospital, Balboa Hospital, Quintard Hospital, Villa View General Hospital, La Mesa (Calif.) Community Hospital, and the Chula Vista (Calif.) Hospital; died Sept. 24, aged 36, of sarcoma.

Gibson, Stanley ⊕ Chicago; born April 9, 1883; Northwestern University Medical School, Chicago, 1913; specialist certified by the American Board of Pediatrics; professor of pediatrics emeritus at his alma mater; member of the American Pediatric Society, Institute of Medicine of Chicago, and the American Academy of Pediatrics; veteran of World War I; served on the staffs of St. Luke's Hospital and the Children's Memorial Hospital; in 1949 DePauw University, Greencastle, Ind., awarded him an honorary doctor of science degree; died in the Veterans Administration Research Hospital Oct. 24, aged 73, of cancer.

Alexander, John Eugene, Charlotte, N. C.; Meharry Medical College, Nashville, Tenn., 1930; consultant, Good Samaritan Hospital; died Sept. 25, aged 53.

Allen, Wilmot B., New York City; Baltimore Medical College, Baltimore, 1898; member of the Medical Society of the State of New York; consulting ophthalmologic surgeon at St. Francis' Hospital; one of the founders of the Bronx Eye and Ear Infirmary, where he was consultant in ophthalmology and for many years secretary of its board of trustees; honorary assistant eye surgeon at New York Eye and Ear Infirmary; died in St. Luke's Hospital Oct. 12, aged 81, of ruptured abdominal aortic aneurysm.

Aydelotte, Benjamin Fisher ⊕ Louisville, Ky.; University of Louisville School of Medicine, Louisville, 1933; member of the Southeastern Surgical Congress; fellow of the International College of Surgeons; veteran of World War II; for many years on the staffs of the St. Joseph Infirmary and Kentucky Baptist Hospital; died Sept. 30, aged 57, of cancer.

Bate, Richard Alexander, Louisville, Ky.; Hospital College of Medicine, Louisville, 1892; formerly on the faculty of his alma mater; served on the staffs of St. Joseph and Norton Memorial infirmaries and SS. Mary and Elizabeth, Kentucky Baptist, and Jewish hospitals; died Oct. 6, aged 85, of uremia and cerebral arteriosclerosis.

Beil, John Wallace ⊕ Kansas City, Mo.; University Medical College of Kansas City, 1901; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology; veteran of the Spanish-American War; on the staff of St. Joseph Hospital; died Sept. 22, aged 81, of arteriosclerosis.

Biggar, Robert John ⊕ Awali, Bahrein Islands in Persian Gulf; Wayne University College of Medicine, Detroit, 1937; veteran of World War II; medical director of the California-Texas Oil Company; died Sept. 21, aged 47.

Blender, William ⊕ Peoria, Ill.; Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, 1904; past-president of the Peoria Medical Society; member and past-president of the staff, St. Francis Hospital, where he died Sept. 27, aged 73.

Borodkin, Howard David, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1953; certified by the

⊕ Indicates Member of the American Medical Association.

National Board of Medical Examiners; resident at the Hahnemann Medical College and Hospital, where he died Oct. 12, aged 31, of carcinoma of the colon.

Boyce, Addisone Schipper, New City, N. Y.; New York Medical College and Hospital for Women, Homeopathic, New York City, 1906; formerly on the faculty of her alma mater; served on the staffs of the Woman's Hospital and the Flower and Fifth Avenue Hospitals in New York City; died in the Doctors Hospital, New York City, Oct. 17, aged 73, of coronary thrombosis.

Brand, Andrew J. ⊕ Prairie, Miss.; Memphis Hospital Medical College, Memphis, Tenn., 1901; died Oct. 6, aged 86.

Brown, James Adlai, Jr. ⊕ Evansville, Ind.; Howard University College of Medicine, Washington, D. C., 1934; veteran of World War II; on the staffs of the Protestant Deaconess Hospital and St. Mary's Hospital, where he died Sept. 25, aged 50, of pancreatitis and hepatitis.

Burhyte, Egbert L. ⊕ Niagara Falls, N. Y.; University of Buffalo School of Medicine, Buffalo, 1911; member of the Industrial Medical Association; fellow of the American College of Surgeons; on the staffs of the Mount St. Mary's Hospital and the Niagara Falls Memorial Hospital, where he was chief of staff and chief of surgery and where he died Sept. 27, aged 70, of cerebral thrombosis.

Carliner, Paul Elliott ⊕ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1934; also a graduate in pharmacy; member of the American Academy of Allergy; veteran of World War II; instructor in medicine at Johns Hopkins University School of Medicine; on the staffs of the Sinai Hospital and the Johns Hopkins Hospital, where he died Oct. 13, aged 46, of a heart attack.

Clayton, Ione Shultz ⊕ Arkansas City, Kan.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1908; died Sept. 16, aged 71, of cerebral hemorrhage.

Collins, Edward Ladow, Grand Rapids, Mich.; Detroit College of Medicine and Surgery, Detroit, 1916; served as superintendent of the Michigan Employment Institute for the Blind in Saginaw; died Sept. 25, aged 77, of cerebral embolism, coronary occlusion, and arteriosclerosis.

Corby, John Francis ⊕ Colonel, U. S. Army, retired, Sonoma, Calif.; Medico-Chirurgical College of Philadelphia, 1913; served in France during World War I; veteran of World War II; entered the Medical Corps of the U. S. Army in 1917 and retired Sept. 30, 1946; died in the Letterman Army Hospital, San Francisco, Oct. 5, aged 64.

Croft, Marion Eugene, Hopkinsville, Ky.; University of Nashville Medical Department, Nashville, Tenn., 1900; Hospital College of Medicine, Louisville, 1902; honorary staff member of the Jennie Stuart Memorial Hospital, where he died Sept. 13, aged 81, of cerebral arteriosclerosis.

Crook, Roy, Downey, Calif.; John A. Creighton Medical College, Omaha, 1905; for many years practiced in Lincoln, Neb.; died Sept. 24, aged 76.

Cross, Earl William, Tarentum, Pa.; College of Physicians and Surgeons, Baltimore, 1908; an associate member of the American Medical Association; fellow of the American College of Surgeons; served on the staff of the Allegheny Valley Hospital; died in the Medical College of Virginia, Hospital Division, in Richmond Sept. 26, aged 69.

Deichler, Lyn Waller, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1903; an associate member of the American Medical Association; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology; consulting ophthalmologist at the Philadelphia General Hospital; died Oct. 2, aged 74, of coronary thrombosis.

Dietsche, Erwin Karl ⊕ Klamath Falls, Ore.; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1910; died Sept. 30, aged 70, of coronary infarction.

Drake, Charles Arthur, Ridgewood, N. J.; Syracuse University College of Medicine, Syracuse, N. Y., 1908; formerly practiced in New York City, where he was on the staff of the New York Eye and Ear Infirmary; died Sept. 19, aged 72, of a heart attack.

Douglass, Charles William ⊕ Anacortes, Wash.; Creighton University School of Medicine, Omaha, 1941; member of the American Academy of General Practice; interned at the Providence Hospital in Seattle; past-president of the Skagit County Medical Association; served as city health officer; veteran of World War II; on the staff of the Anacortes Hospital; died Sept. 10, aged 41, of coronary occlusion.

Elfeld, Edward A., Arlington Heights, Ill.; Homeopathic Medical College of Missouri, St. Louis, 1891; died in St. Anthony Hospital, Denver, Oct. 5, aged 88, of arteriosclerotic heart disease.

Escue, Henry Merritt, Charleston, W. Va.; Medical College of Virginia, Richmond, 1932; specialist certified by the American Board of Urology; an associate member of the American Medical Association; member of the American Urological Association; fellow of the American College of Surgeons; veteran of World War II; served as mayor of St. Albans; past-president of the Kanawha Medical Society; died in the Charleston General Hospital Oct. 17, aged 53, of astrocytoma.

Ferris, John Charles ⊕ Senior Surgeon, U. S. Public Health Service Reserve, Texarkana, Texas; Laval University Faculty of Medicine, Quebec, Canada, 1940; chief medical officer for the Federal Correctional Institute; died in Long Beach, Calif., Sept. 21, aged 44, of cerebral hemorrhage and hypertension.

Floyd, Thomas J., Abbeville, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; member of the Medical Association of the State of Alabama; served as city commissioner and Henry County health commissioner; formerly health officer of Houston County; died Sept. 25, aged 72, of coronary disease.

Foley, Edward Paul, Miami, Fla., Albany Medical College, Albany, N. Y., 1899; died Sept. 2, aged 82, of arteriosclerosis.

Ford, Ada, Mansfield, Ohio; University of Wooster Medical Department, Cleveland, 1909; died Sept. 28, aged 80.

Fort, Richard George ⊕ Glenview, Ill.; University of Illinois College of Medicine, Chicago, 1939; member of the American Academy of General Practice; veteran of World War II and was awarded the Bronze Star; on the staff of St. Francis Hospital in Evanston; died Oct. 2, aged 41, of acute myocardial infarction and arteriosclerotic heart disease.

Frank, John Henry, Neillsville, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1896; died Aug. 29, aged 86, of coronary occlusion.

Gates, Benjamin Franklin ⊕ Cleveland, Tenn.; Medical Department of Grant University, Chattanooga, 1898; died Sept. 28, aged 94.

Gelow, John E., Grand Island, Neb., Northwestern University Medical School, Chicago, 1905; died in St. Joseph's Hospital, Brainerd, Minn., Sept. 22, aged 76.

Gibner, George P., Spearman, Texas; University of Texas School of Medicine, Galveston, 1897; died in the Hansford County Hospital Sept. 28, aged 83.

Gibson, Charles Francis, Burlington, N. J.; Howard University College of Medicine, Washington, D. C., 1931; formerly practiced in Mobile, Ala., where he was psychiatrist for the Veterans Administration and on the staff of the Blessed Martin de Porres Hospital; served on the board of health; died in the Deborah Tuberculosis Sanatorium, Browns Mills, Sept. 5, aged 50, of heart disease.

Glafke, William Harley ⊕ New York City; Northwestern University Medical School, Chicago, 1911; interned at the Cook County Hospital in Chicago; specialist certified by the American Board of Internal Medicine; consulting gastroenterologist at the Woman's Hospital; consulting physician in gastroenterology at St. Luke's Hospital, where he died Oct. 1, aged 70, of coronary thrombosis.

Gouldin, John Milton ⊕ Tappahannock, Va.; Medical College of Virginia, Richmond, 1904; past-president of the Mid-Tidewater Medical Society; died Sept. 10, aged 77.

Gray, Albert Newton ⊕ Burlington, Kan.; University of Kansas School of Medicine, Kansas City, 1907; served as county health officer and county coroner; on the staff of the Coffey County Hospital, where he died Sept. 20, aged 86, of cardiorenal vascular disease.

Gray, Henry Arthur ⊕ Keokuk, Iowa; College of Physicians and Surgeons, Keokuk, 1895; Keokuk Medical College, College of Physicians and Surgeons, Keokuk, 1900; fellow of the American College of Surgeons; past-president of the Iowa State Medical Society; veteran of World War I; for many years on the staffs of Graham Hospital and St. Joseph's Hospital, where he died Sept. 23, aged 83.

Guenther, Leo Peter ⊕ Los Angeles; Western Reserve University School of Medicine, Cleveland, 1923; member of the American Academy of General Practice; on the staff of the California Hospital, where he died Aug. 22, aged 58, of uremia.

Hallarman, Harry, New York City; University and Bellevue Hospital Medical College, New York City, 1913; died Oct. 9, aged 73, of coronary occlusion.

Havey, Leroy Austin, Bridgeport, Conn.; University of Vermont College of Medicine, Burlington, 1910; member of the Connecticut State Medical Society; served as treasurer of the Fairfield County Medical Association; died Sept. 28, aged 71, of acute myocardial infarction.

Hartzell, Solomon Mayer, Beverly Hills, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the International College of Surgeons and the American College of Surgeons; formerly practiced in Youngstown, Ohio, where he was on the staff of the Youngstown Hospital; died in the Cedars of Lebanon Hospital, Los Angeles, Sept. 10, aged 76, of heart disease.

Heath, J. Mott, Greenport, N. Y.; College of Physicians and Surgeons, Baltimore, 1913; member of the Medical Society of the State of New York; examining physician for Greenport public schools; for many years president of the board of trustees and chief of staff of Eastern Long Island Hospital in Greenport; county coroner; died Sept. 20, aged 78, of arteriosclerosis.

Heim, John W. ⊕ Louisville, Ky.; Louisville Medical College, Louisville, 1904; member of the American Society of Anesthesiologists; served on the staffs of the SS. Mary and Elizabeth Hospital, St. Anthony Hospital, Jewish Hospital, Childrens Hospital, and the Kentucky Baptist Hospital, where he died Sept. 25, aged 75, of bronchogenic carcinoma, duodenal ulcer, and cholelithiasis.

Hinrichs, August Gustav, West Pittston, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900, an associate member of the American Medical Association; served overseas during World War I; member of the staff of the Pittston Hospital, where he died Sept. 1, aged 80.

Hoffman, J. Omer ⊕ Chester, Ill., University of Arkansas School of Medicine, Little Rock, Ark., 1934; member of the American Academy of General Practice; past-president of the Randolph County Medical Society; vice-president of the medical staff of St. Clement's Hospital in Red Bud; veteran of World War II; died Sept. 4, aged 49, of coronary thrombosis.

Holt-Harris, John Evan, Albany, N. Y.; Albany Medical College, Albany, 1929; served as professor of bacteriology at his alma mater; formerly city bacteriologist; formerly on the staffs of the Willard Parker Hospital in New York City and the Albany Hospital, where he died Oct. 14, aged 79, of carcinoma of the sigmoid.

Hunt, Donald Jay ⊕ Senior Surgeon, U. S. Public Health Service, retired, Los Angeles; Northwestern University Medical School, Chicago, 1927; retired from the U. S. Public Health Service June 1, 1952; died Sept. 17, aged 56, of myocardial infarction.

Jameson, William Beatty, Bethlehem, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1886; served on the staff of the Hamburg State Sanatorium for Tuberculosis No. 3 in Hamburg; died Sept. 8, aged 96, of pulmonary edema.

Jenkins, George Bain, Washington, D. C.; Hospital College of Medicine, Louisville, Ky., 1898; professor emeritus of anatomy at the George Washington University School of Medicine; died Oct. 6, aged 81, of a heart attack.

Jennings, Cyrus Packard, Macedon, N. Y.; University of Buffalo School of Medicine, Buffalo, 1894; an associate member of the American Medical Association; died in the Park Avenue Hospital in Rochester, Aug. 22, aged 83, of arteriosclerosis.

Josey, Thomas Walter, Augusta, Ga.; Howard University College of Medicine, Washington, D. C., 1912; member of the board of directors of the Pilgrim Health and Life Insurance Company; died in Washington, D. C., Aug. 31, aged 75.

Kennedy, Edwin Jay, Houston, Texas; University of Texas School of Medicine, Galveston, 1918; retired chief medical examiner for the Army recruiting station; veteran of World War I; died Oct. 2, aged 64, of coronary thrombosis.

King, Luther John ⊕ Meadville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1922; formerly secretary of the Crawford County Medical Society; formerly practiced in Conneautville, where he was a member of the school board; past-president of the Pennsylvania Allergy Association; for many years county coroner; on the staff of the Spencer Hospital; died Aug. 29, aged 59, of coronary thrombosis.

Krampert, Frank Lawrence ⊕ Auburn, Neb.; University of Nebraska College of Medicine, Omaha, 1921; died in the Auburn Hospital Aug. 24, aged 62, of cerebral hemorrhage.

Kuttler, Leonard William, Cleveland; Ohio State University College of Homeopathic Medicine, Columbus, 1915; died in the Euclid-Glenville Hospital Oct. 2, aged 72, of cerebral thrombosis.

Lapp, John G. ⊕ Kansas City, Mo.; University Medical College of Kansas City, 1897; formerly member of the city council; on the staffs of the Research Hospital and the Menorah Hospital Medical Center, where he died Sept. 23, aged 86, of prostatic hypertrophy.

Lawrence, Henry Dolson ⊕ Marietta, Pa.; Temple University School of Medicine, Philadelphia, 1930; Marietta school examiner; on the staff of the Columbia (Pa.) Hospital; died in the Lancaster (Pa.) General Hospital Oct. 1, aged 54.

Leonard, Frederick Jerome, Ilion, N. Y.; Syracuse University College of Medicine, Syracuse, 1911; an associate member of the American Medical Association; veteran of World War I; on the staff of the Ilion Hospital; died Sept. 22, aged 70, of cancer.

Levi, Max, New York City; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1923; member of the International College of Surgeons; on the staffs of the Mount Sinai Hospital and the Kew Gardens (N. Y.) General Hospital; died Oct. 9, aged 61, of a heart attack.

McKnight, William Burney ⊕ Mansfield, Texas; University of Louisville Medical Department, Louisville, Ky., 1886; died Oct. 1, aged 97.

Manny, Mary Alice ⊕ Laguna Beach, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1927; on the staff of the Hoag Memorial Hospital–Presbyterian, Newport Beach; died Oct. 4, aged 63, of cancer of the throat.

Marlowe, William Anderson, Walstonburg, N. C.; Jefferson Medical College of Philadelphia, 1919; member of the Medical Society of the State of North Carolina; served as president of the Greene County Medical Society; veteran of World War I; died in the Woodard-Herring Hospital, Wilson, Sept. 29, aged 65, of heart disease.

Martin, James Calvin, Pulaski, Va.; University of Virginia Department of Medicine, Charlottesville, 1934; veteran of World War II; member of the Medical Society of Virginia; on the staff of the Pulaski Hospital; died Aug. 12, aged 48, of myocardial infarction.

Mason, Lyman Whidbee ⊕ Denver; University of Colorado School of Medicine, Denver, 1925; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; formerly on the faculty of his alma mater; member of the staffs of St. Joseph's Hospital and the Presbyterian Hospital; served as acting scientific editor of the *Rocky Mountain Medical Journal*; died Aug. 29, aged 60.

Massenburg, George Yellott ⊕ Macon, Ga.; University of Maryland School of Medicine, Baltimore, 1911; fellow of the American College of Surgeons; veteran of World War I; consultant, Macon Hospital; died in St. Mary's Hospital, Rochester, Minn., Sept. 1, aged 68, of embolus to coronary artery with heart failure and acute bacterial endocarditis.

Mauboules, Jean Paul, Jr., Rayne, La. (licensed in Louisiana in 1899); past-president of Rayne State Bank; died Sept. 30, aged 87.

Pan, Oscar ⊕ Cleveland; Deutsche Universität Medizinische Fakultät, Prague, Austria, 1902; served on the staff of St. Alexis Hospital; died Sept. 5, aged 79, of cardiovascular renal disease.

Parkerson, Isaac Jefferson, Eastman, Ga.; University of Georgia Medical Department, Augusta, 1917; veteran of World War I; died in the Veterans Administration Hospital, Dublin, Aug. 30, aged 67, of arteriosclerosis.

Porter, Arthur Silas ⊕ Salem, Ill.; Loyola University School of Medicine, Chicago, 1916; died Aug. 25, aged 81.

Price, Chester Arthur ⊕ Chicago; Eclectic Medical College, Cincinnati, 1919; formerly on the faculty of his alma mater; veteran of World War I; on the courtesy staff of the Franklin Boulevard Community Hospital, staff member at St. Bernard's Hospital, where he died Oct. 1, aged 62, of coronary occlusion.

Rogers, George McKinley, Philadelphia; Temple University School of Medicine, Philadelphia, 1921; died in the Lankenau Hospital Sept. 9, aged 59, of nephrosclerosis.

Shaffer, Stanley Norman, Forest Hills, N. Y.; Universität Bern Medizinische Fakultät, Switzerland, 1935; member of the American College of Chest Physicians and the American Trudeau Society; veteran of World War II; consultant on chest diseases to the New York City Health Department; attending physician at Triboro Hospital of Queens Hospital Center in Jamaica; died in the New York Hospital in New York City Sept. 16, aged 46, of coronary occlusion.

., Ansly Thomas ⊕ Edgerton, Wis.; College of Physicians Surgeons of Chicago, School of Medicine of the University Illinois, Chicago, 1907; veteran of World War I; on the staff of the Edgerton Memorial Community Hospital, where he died Sept. 3, aged 74, of cerebral thrombosis.

Sloan, George H., Mineral Point, Pa.; Cincinnati College of Medicine and Surgery, Cincinnati, 1885; died Sept. 4, aged 89, of carcinoma of the floor of the mouth.

Smith, Joseph ⊕ Greenville, N. C.; Medical College of Virginia, Richmond, 1914; died Sept. 23, aged 66.

Sparkman, Arthur Alphonzo ⊕ Thomasville, Ga.; College of Physicians and Surgeons, Memphis, Tenn., 1910; on the staff of the Veterans Administration; died in the Kennedy Veterans Administration Hospital, Memphis, Tenn., Sept. 14, aged 68, of carcinoma of the nasopharynx with metastases to the mediastinum, lung, and liver.

Spickschen, Henry F. ⊕ New York City; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1916; served on the staff of the Lenox Hill Hospital; died in Mexico City while on a vacation Sept. 30, aged 66.

Stacy, Archie Jackson ⊕ Tupelo, Miss.; Tulane University School of Medicine, New Orleans, 1918; specialist certified by the American Board of Radiology; served as secretary-treasurer of Northeast Mississippi Medical Society; member of the board of trustees of the Blue Mountain (Miss.) College; on the staff of the North Mississippi Community Hospital, where he died Sept. 29, aged 68, of coronary thrombosis.

Stickley, William Thomas ⊕ White Hall, Ill.; University of Illinois College of Medicine, Chicago, 1931; veteran of World War I; died Sept. 5, aged 58, of coronary disease.

Strobel, William George ⊕ Duluth, Minn.; Rush Medical College, Chicago, 1912; fellow of the American College of Surgeons; on the staffs of St. Luke's Hospital, Miller Memorial Hospital, and St. Mary's Hospital, where he died Sept. 20, aged 70, of acute myocardial infarction and hypertension.

Stroud, Homer Anderson ⊕ Jonesboro, Ark.; Memphis Hospital Medical College, Memphis, Tenn., 1903; fellow of the American College of Surgeons; formerly president of the Craighead County Medical Society, and vice-president of the Arkansas Medical Society; one of the founders and for many years president of the Craighead County Tuberculosis Association; chief of staff emeritus at St. Bernard's Hospital, where he died Oct. 1, aged 81, of paralysis agitans.

Thomson, Herbert Sedgefield, Corte Madera, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1909; an associate member of the American Medical Association; formerly on the faculty of the University of California School of Medicine in San Francisco; veteran of World War I; served as chief surgeon of the Standard Oil Company; died Sept. 7, aged 73, of cancer of the esophagus.

Trapp, Anthony Nicholas ⊕ Chicago; Rush Medical College, Chicago, 1925; veteran of World War II; on the staff of St. Joseph Hospital, where he died Oct. 14, aged 59, of cerebral embolism.

Traugh, George Holton ⊕ Fairmont, W. Va.; University of Pittsburgh School of Medicine, Pittsburgh, 1919; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past-president and secretary of the Marion County Medical Society; on the staff of the Fairmont General Hospital, where he died Sept. 19, aged 66, of coronary disease.

Vinsant, William Jonathan ⊕ San Benito, Texas; University of Tennessee College of Medicine, Memphis, 1900; member of the House of Delegates of the American Medical Association; on the staff of the Dolly Vinsant Memorial Hospital; died July 14, aged 82, of cerebral hemorrhage.

Ward, Thomas Leo ⊕ Arnolds Park, Iowa; State University of Iowa College of Medicine, Iowa City, 1926; member of the American Academy of General Practice; served as president of the school board; on the staffs of the Marcus Snyder Memorial Hospital in Spirit Lake and the Holy Family Hospital in Estherville; died Sept. 10, aged 59, of carcinoma of the bladder.

Willis, Hillary T., Hyattsville, Md.; University College of Medicine, Richmond, Va., 1898; five times mayor of Hyattsville; died in the Eugene Leland Memorial Hospital in Riverdale Sept. 12, aged 83.

Wright, John Bryan, Raleigh, N. C.; University College of Medicine, Richmond, Va., 1899; member of the Medical Society of the State of North Carolina; past-president of the Wake County Medical Society and the Raleigh Academy of Medicine; formerly member of the state board of health; on the staffs of the Mary Elizabeth Hospital, St. Agnes Hospital, and the Rex Hospital, where he died Sept. 29, aged 82, of a dissecting aneurysm.

Yarnell, Helen ⊕ New York City; College of Medical Evangelists, Loma Linda and Los Angeles, 1932; specialist certified by the American Board of Psychiatry and Neurology; certified by the National Board of Medical Examiners; member of the American Psychiatric Association; died in the French Hospital Sept. 8, aged 52, of Hodgkin's disease.

Yoder, Homer Maple ⊕ Smithville, Ohio; University of Wooster Medical Department, Cleveland, 1906; died Sept. 30, aged 83.

BRAZIL

Chlorpromazine in Psychiatry.—Dr. Spartaco Vizzotto and co-workers (*Arq. Depart. assist. psicopat.* 21:21, 1955) distinguish a "psychoplegic" action of chlorpromazine responsible for its effects on endogenous psychoses and a "neuroplegic" action of the drug related especially to cerebral circulation and edema. Observing the vessels of the fundus oculi during the injection of chlorpromazine intravenously, they noticed their reduction to about one-third of their original caliber. They interrupted a state of insulin coma with epinephrine and then investigated the influence of chlorpromazine. They concluded that the latter drug inhibits the action of the epinephrine. Although the authors do not claim that the result in their series of 71 cases is conclusive, it seems to confirm the favorable results reported in the literature on confusional psychoses of toxic or infectious origin in patients in whom anxiety predominates and in patients with status epilepticus or delirium tremens. In most patients with acute psychomotor excitement they obtained a tranquilizing effect but without remission of other symptoms, even in those who were affected only episodically. The symptoms of chronically excited patients were generally relieved to such an extent that they could return to their families. The authors also used chlorpromazine in patients with general paralysis who were intensely agitated and observed a prompt tranquilizing effect. In two patients who underwent a prolonged course of treatment with the drug, the spinal fluid used in the Wassermann reaction became entirely negative.

Schistosomal Cor Pulmonale and Myocarditis.—Dr. de Barros and co-workers (*Arquivos dos Hospitais da Santa Casa de São Paulo,* March, 1956) reported on two patients in whom cor pulmonale was a direct consequence of schistosomal infestation. The first patient had dyspnea, gallop rhythm, venous stasis, and tachycardia. The late stage of American trypanosomiasis had to be ruled out. The right bundle-branch block, as seen in the electrocardiogram, was also suggestive of trypanosomiasis. The presence of a generalized myocarditis with an eosinophil exudate explained the clinical and electrocardiographic similarities between the two diseases. In the second patient the pathologist's findings (intense pulmonary arteritis, arteriovenous fistulas, and generalized pulmonary sclerosis) explained the clinical manifestations. Ova were removed from the lumen by endothelial activity. The dissemination of the ova throughout the arterial circulation occurred through the arteriovenous fistulas and through the migration of ova from the arterial system into the pulmonary venous system through the loose intervascular connective tissue. Furthermore, the parasitic activity by means of ova was increased because they were laid in organs that normally do not constitute the habitat of the parasite. Adult male and female schistosomes were found in the brain and the heart. The severe involvement of the pulmonary arterioles explained the chronic cor pulmonale. The main cause of the hypertension was the serious arteritis, which was diffuse. This was an allergic reaction against the parasite and the ova. The eosinophil myocarditis had the same pathological background, the parasite and ova being found in the lungs and the heart.

Akinetic Mutism.—At the meeting on June 5, 1956, of the Associação Paulista de Medicina, Drs. Tenuto and Longman discussed two patients with akinetic mutism. One patient had a rhabdomyosarcoma in the left cerebellar hemisphere with bulbar compression. The other patient had a neurinoma in the left cerebellopontine angle, with atrophy by compression of the surrounding tissue. Akinetic mutism may be caused by rupture of the functional harmony of the brain through activation of an inhibitory mechanism in the cortex. According to this concept and based on modern neurophysiological research on the cerebellum, the authors admit that the lesions found in the cerebellum in the two cases reported may be responsible for the akinetic mutism through suppressive mechanisms located in the reticular system. They suggest, therefore, that the cerebellum may be included in the structural system, changes in which may cause akinetic mutism, which other authors have already connected with lesions in the mesencephalodiencephalic region and, at cortical levels, in the anterior part of the cingulate gyri.

Surgery in Children.—Dr. A. Amorim (*Rev. paulista med.* 49:61, 1956) investigated the metabolic rate in children and the meaning of its increase by such causes as pain and nervous instability. An adequate preanesthetic medicament helps to minimize the chances of shock and of nervous disturbances. Operation on infants requires great attention to details if serious complications are to be avoided. The loss of body heat, bleeding, and surgical trauma during an operation should be kept to a minimum. A child who is in a good state of hydration and nutrition and is free of respiratory or digestive diseases does not usually have any serious postoperative complications. Operative complications are due to poor surgical management or a poor general condition due to the disease itself. Water and electrolyte balance are of the utmost importance in the child. Alkalosis (a common complication due to continuous vomiting), acidosis, sodium and potassium deficiencies, and salt retention are hazards to be watched for.

Obstructive Jaundice.—At a staff meeting of the Medical School of the University of São Paulo, Dr. H. M. Sadek discussed obstructive jaundice. According to his experiments on dogs, there is a greater quantity of total direct-reacting bilirubin in the splenic, mesenteric, and renal veins than in the aorta. It is also greater in the infrahepatic than in the suprahepatic segment of the inferior vena cava. There is a greater quantity of late-reacting bilirubin in the mesenteric and renal veins than in the aorta and in the portal vein and infrahepatic inferior vena cava than in the suprahepatic vena cava. No changes in prompt-reacting bilirubin and indirect bilirubin in the first week of experimental obstructive jaundice were observed. In the spleen, intestines, and kidneys there is a greater quantity of total bilirubin and total direct-reacting bilirubin in the venous blood than in the arterial blood. In the liver the blood that leaves the organ has less direct-reacting bilirubin than the blood that enters it. Dr. Sadek admits the extrahepatic origin of bilirubin, which in no way disproves the liver's ability to form biliary pigment. His results suggest an intracellular production of bilirubin.

FRANCE

Colostrum Extract and Pituitary Gonadotropin.—R. Moreau and co-workers (*Presse méd.* 64:1545, 1956) gave a nonsaponifiable colostrum extract to mice but observed no change in them except for a slight loss of weight when large doses were given. In contrast to injections of estrogens, androgens, and progesterone, the injection of this extract had no gross effect on the genital tract of the immature mice. Histologically it caused some alterations in the epithelium, which assumed a mucosal appearance. The alterations are similar to but less marked than those obtained with large doses of androgens. After saturation with the colostrum extract, the injection of estrone or progesterone promotes an increase in the weight of the uterus, but the extract seems to potentiate only the action of estrogens and not that of progesterone. In no case is there any inhibiting effect. In animals treated with colostrum extract, then injected with pituitary gonadotropin, the phenomena proper to this hormone are not observed; specifically there is no increase in the weight of the uterus and no keratinization of the vagina. Romani and Quantius, using virgin does, believe the appearance of a hemorrhagic follicle to be a positive test for the follicle-stimulating hormone. This test is rendered negative by the injection of a sterolic extract of colostrum. The extract appeared to inhibit the response of the ovarian receptor to the pituitary stimulation.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Lung Cancer.—G. Brouet and co-workers (*Presse méd.* 64:1548, 1956) report that alveolar carcinoma of the lung is a rare form of intrathoracic tumor. They observed a case in a 55-year-old woman whose clinical symptoms first appeared eight years before she died. In her last years she had a profuse bronchorrhea, with expectoration of more than 1 qt. of sputum a day. The authors point out that certain cases of intractable bronchorrhea that have been previously reported might have been associated with an unrecognized alveolar epithelioma. In the authors' case, no extrathoracic tumor was found, thus excluding the possibility of its being metastatic in origin.

Bone Lacunas in the Cranial Vault.—P. Wertheimer and co-workers (*Presse méd.* 64:1556, 1956) report that bone lacunas in the cranial vault may be classified in the following ways: (1) traumatic congenital; (2) inflammatory due to syphilis, tuberculosis, osteomyelitis, or a mycosis; (3) due to a primary tumor, benign tumor, metastatic tumor, or neighboring tumor, such as a meningioma; (4) due to diseases of the hematopoietic system, such as myeloma, chloroma, Hodgkin's disease, and various anemias; (5) due to bone dysplasia (reticulosis, such as lipoid granulomatosis or xanthomatosis, eosinophilic granuloma, Paget's circumscribed osteoporosis, Jaffe and Lichtenstein's dysplasia, or fibrous osteitis); (6) endocrine osteoses, such as parathyroid fibrocystic osteosis, exophthalmic goiter, pituitary basophilism, Milkman's syndrome, and postmenopausal osteoporosis; and (7) cysts in the cranial vault associated with multiple neurofibromatosis. Because there are so many causes, the diagnosis cannot be made on the basis of the reading of the roentgenogram alone.

Chemotherapy of Tuberculosis.—Pestel and Ravina (*Presse méd.* 64:1577, 1956) stated that certain advantages derive from adding drugs with an anti-inflammatory action to those specifically antibacterial agents commonly used. Both phenylbutazone and aminopyrine with phenylbutazone proved particularly effective in this respect because of their practically constant control of the inflammatory reactions of tuberculosis. The authors, by giving equal amounts of isoniazid and phenylbutazone simultaneously, obtained remarkable results in the treatment of erythema nodosum, primary tuberculosis, and serofibrinous pleurisy. This treatment was well tolerated.

Tetracycline and Experimental Infections.—J. C. Levaditi and co-workers (*Presse méd.* 64:1579, 1956) treated repeated experimental infections in mice induced by intraperitoneal injections of cultures of Salmonella typhosa, Escherichia coli, *Diplococcus pneumoniae*, or Micrococcus pyogenes var. aureus with tetracycline. The infections were well tolerated in spite of their being repeatedly induced. Although the strains used were virulent, many animals developed a resistance to infection as a result of repeated contact and antibiotic treatment. The time required for the appearance of this resistance as well as its duration varied with the bacterial species used and with the individual mouse. In some of the mice the acquired resistance persisted and in others it disappeared rapidly. Similar reactions are observed when streptomycin is used in place of tetracycline.

PERU

Chlorpromazine and Mental Diseases.—Although chlorpromazine is not a specific cure for the psychoses, it is one of the most important tools of modern psychiatry for the management of mental diseases, and, when used with insulin and/or electroshock therapy, it renders the therapeutic results more satisfactory than does any other form of treatment, according to Drs. M. Querol and M. Chicata, of the National University of San Marcos, in an address before one of the meetings of the centennial celebration of the Faculty of Medicine of Lima. They compared the therapeutic results in groups of schizophrenic patients. In the series in which chlorpromazine was given alone or with electroshock therapy, 98% of the patients were benefited in some degree, whereas in the groups treated otherwise only 71% were benefited, despite the number of patients in whom the disease was of shorter duration than in the former. The best results were observed when chlorpromazine was combined with insulin. The authors advance the hypothesis that the therapeutic effects of shock therapy and chlorpromazine reinforce each other. They gave chlorpromazine to 50 patients with schizophrenia, 12 with manic-depressive psychosis, and 9 with chronic alcoholic psychosis. Therapy was started with minimal dosage, which varied according to the severity of the disease, and was slowly increased until the optimal dosage was reached. This dosage was maintained for a variable period suitable to permit the best clinical response, and then it was reduced gradually to the minimal maintenance dose. All patients received chlorpromazine by mouth, but those showing great agitation were given the drug intramuscularly for the first few days.

In the group of schizophrenic patients about 90% of those who had had the disease more than a year had previously failed to respond to other forms of treatment. Only those patients unresponsive or unsuitable for shock therapy were considered in the first trial, but the strikingly favorable results obtained in these patients encouraged the authors to use chlorpromazine in patients who had had no previous treatment. The period of active treatment, from the onset of the therapy to the establishment of the maintenance dose, ranged from 24 to 261 days. The average maintenance dose was 100 mg. daily. The drug was given alone in 26 patients and with shock therapy in the rest. Promethazine hydrochloride and barbiturates were given to induce sleep in some patients in whom insomnia paradoxically followed the administration of chlorpromazine or if the patient had to be given the drug for a long time. Promethazine and stramonium powders proved useful in diminishing or preventing the paralysis agitans induced by chlorpromazine. Promethazine also prevented skin eruptions, which, when present, were in no case severe enough to warrant the discontinuance of the therapy. In nine disturbed and agitated patients, reserpine was given as an adjuvant in doses of from 1 to 4 mg. daily over a mean period of one month. Vitamins, particularly of the B complex, and mild laxatives were given routinely. In the group of patients who had had the disease one year or less, 85% obtained a total remission and 15% a social remission, whereas in the group of patients who had had the disease more than a year, only 24% obtained a total remission, in 32% there was a social remission, in 35% slight improvement, in 3% no improvement, and 6% died. Patients with the paranoid, catatonic, and paranoid-catatonic types of schizoprenia showed the best results. Chlorpromazine definitely proved more beneficial when used with shock therapy than when used alone.

The tranquilizing effect of the drug was especially striking, the agitation subsided generally within the first week of therapy, and both anxiety and psychomotor hyperactivity were greatly reduced. Some morbid states, such as fear and anguish, yielded to the drug long before mental disturbances of psychic spheres other than the affect responded. The patients became better aware of their environment and became accessible for concurrent psychotherapy. Hallucinations became less severe in the fourth to sixth week of therapy, but disturbed ideation was found to be the symptom most resistant to treatment. Late in the course of the treatment the improved patients began to realize the unreality of their delusions. Some patients had no memory for the delusions they harbored during their period of agitation. From the first days of treatment slowness of motion was noticed in several patients. Amimia and involuntary movements were not unusual findings, and a reversible paralysis agitans–like syndrome was observed in 64% of the patients in the series. Late in the course of the treatment, seven patients showed melanoid hyperpigmentation of the face; four, clouding of the consciousness, four, vomiting and diarrhea; two, acute pneumonopathy, two, unexplained fever, one, muscular atrophy; and one, edema

Two patients died during the trial. One of these was in the fourth month of therapy and at that time was taking 500 mg. of chlorpromazine and 4 mg. of reserpine daily. He showed a frank paralysis agitans–like syndrome. Suddenly he developed a high fever and went into shock. His medication was stopped at once, but he died two days later. Chlorpromazine was thought to be the immediate cause of death in this patient; but, in the other, bronchopneumonia and anasarca occurring at the end of the second week of treatment caused the death. Of the 38 patients who were discharged from the hospital, only 18 could be followed up. In 16 of them the remission lasted 2 to 12 months. Several were, when last seen, still receiving the daily maintenance dose under close medical supervision. The other two patients relapsed, one after a month and one after a year outside the hospital. Active therapy must be continued for 2 to 4 months and the maintenance dose taken for an indefinite period in order to prevent relapses. It is likely that larger doses than those used thus far can be given for prolonged periods with even better results than those reported.

As regards the patients with manic-depressive psychosis, seven were in the manic phase and five in the depressed phase. The time elapsed between the onset of the current phase and the beginning of the treatment ranged from 15 days to 4 months in the former and from 3 to 8 months in the latter. The duration of active therapy was 12 to 68 days for those in the manic phase and from 48 to 128 days for those in the depressed phase. The optimal dosage was 100 to 500 mg. daily in the first group and 25 to 300 mg. daily in the second group. In three manic patients, electroshock therapy was also used; this treatment was also used on all patients in the depressed phase. The results were dramatic in the manic patients. All recovered completely except two who died from causes not attributable to chlorpromazine. The mental symptoms improved earlier than in the schizophrenic patients. Within a month of the beginning of therapy almost all the symptoms had subsided. In one patient in whom the medication was abruptly stopped the symptoms returned but subsided again when therapy was resumed. Although in the depressed patients the symptoms subsided within 30 to 60 days of starting therapy, the authors belive that in these patients chlorpromazine acts as an adjuvant to electroshock therapy.

In the alcoholic patients the duration of the psychosis varied from 15 days to 4 months. Active therapy was given for 10 to 45 days, and in no patient was maintenance treatment required. The daily dose ranged from 50 to 200 mg. All the patients were given vitamins and lipotropic agents. In three, electroshock therapy was also used. Complete remission of the psychosis was observed in all the patients. The favorable effect of the drug on tremors was particularly striking.

Radioactive Iodine in Hyperthyroidism.—At the same meeting Drs. J. Correa and F. Moncloa, of the Arzobispo Loayza Hospital of Lima, reported that radioactive iodine is a safe, effective, inexpensive therapeutic agent for patients with hyperthyroidism. In their series of 30 patients treated with this agent, three had previously undergone a thyroidectomy that failed to cure the disease. A single dose of I^{131}, varying from 4 to 15 mc., was given to all patients. Three patients were observed for more than 6 months, 7 for three months, 8 for two and a half months, and 12 for one month or less. The disease was completely arrested in the three patients of the first group, one of whom showed mild transient signs of hypothyroidism. In the second group, five patients became euthyroid and the other two, although improved, still showed slight manifestations of hyperthyroidism. In the third group, two were cured, five were improved, and the remaining one was thought to need another dose of I^{131}. In the fourth group, the follow-up period was too short to justify any conclusions, but significant relief of symptoms was observed in all. In none of the patients whose disease was completely arrested by I^{131} has a relapse been reported. The authors believe that in the patients treated with I^{131} complete control of the hyperthyroidism does not occur in less than three months after the first dose. For this reason a second dose of I^{131} should never be given after the first dose.

Infertility.—At the same meeting Didedle and Tietze stated that in 86% of normal couples pregnancy occurs in the first year of marriage and in 95% it occurs in the first two years. It is generally believed that the age of the wife plays an important role in fecundation and that her chances of becoming pregnant early in the course of marriage diminish as she grows older. A report concerning 160 infertile couples was presented by Dr. Carlos Muñoz T. In all cases the cause of the sterility was determined. Obstruction or occlusion of the oviducts was present in 49.36%. This high incidence of tubal lesions was probably due to the fact that the author's series included only hospital patients, in whom gonococcic postabortive and postpartum infections are common. In 375 insufflations on these patients, 15 being the greatest number made on any one patient, there were no complications; 12 of 79 patients in this group subsequently became pregnant. In 28 women, or 17.5%, an ovarian factor was found to account for the sterility. Disturbances of the follicular phase were found in 18 of them, and 10 had a faulty progestational phase. Thyroid dysfunction was found in 11 patients, who showed either frank signs of hypothyroidism or subclinical hypothyroidism (a basal metabolic rate of about—10, a blood cholesterol level close to the maximal normal value, and a sterility counteracted by thyroid extract). In two patients the urinary 17-ketosteroids were found to be increased. Seven patients, or 25.9%, became pregnant after proper treatment.

A cervical factor was thought to play an important role in the sterility in 18 women, or 11.25%. In seven of them pregnancy followed adequate therapy. Genital tuberculosis was found in 9 patients, in all of whom the course of the disease had been insidious and evidence of tuberculosis in other organs had been lacking. The diagnosis was made by means of endometrial biopsy. Congenital malformations were found in two patients, uterine myoma in two, a large dermoid ovarian cyst in one, and a bilateral tubo-ovarian endometriosis in one. In 20 cases it was the husband who was sterile. In the 77 husbands examined, 55 had normal sperms, 18 had defective sperms, and 4 had no sperms in their seminal fluid.

Mitral Stenosis.—At the same meeting Dr. G. Whittembury and co-workers reported that no systematic increase in the proportionate amount of blood contained in the lungs arises in mitral stenosis. Their study included 4 men and 16 women. In seven patients the stenosis was grade 2, in six it was grade 3, and in seven grade 4. Operation verified the diagnosis in six of the patients, none of whom showed mitral insufficiency. The circulation time, cardiac index, pulmonary blood volume, intrathoracic blood volume, and total blood volume of these patients were compared with those of normal persons. All patients were studied in basal conditions after a rest of at least 45 minutes. It was found that the circulation time increases, the cardiac index decreases, and the blood volume increases with the increasing severity of the disease. Mean values of the circulation time showed almost equivalent variations in patients with grade 2 and 3 stenosis but were significantly less in those with grade 4 stenosis. No difference was observed between the cardiac index of those with grade 2 and 3 stenosis, but this index was significantly lower than in patients with grade 4 stenosis. The difference between the normal values of total blood volume and those of patients with grade 2 stenosis was not significant, but the volume was less than that of those with grade 3 stenosis and much less than that of patients with grade 4 stenosis. Expressed as absolute values the increase of the pulmonary blood volume paralleled the severity of the disease, but expressed as a percentage of the total blood volume the increase was only significant in patients with grade 3 stenosis. Although the values of the intrathoracic blood volume tended to increase with the severity of the disease, the difference between the mean values of normal subjects and of patients with mitral stenosis was not statistically significant. A statistically significant correlation was found between pulmonary blood volume and intrathoracic blood volume.

Acute Failure of the Left Ventricle.—At the same meeting Dr. Victor Alzamora Castro, head of the department of cardiology of the Dos de Mayo Hospital, recommended massage of the carotid sinus in patients with acute insufficiency of the left ventricle associated with hypertension. He used this treatment in a series of 31 patients and brought the crisis under control in 26. In some patients the response was prompt and dramatic, consisting of alleviation of the pulmonary signs, relief of dyspnea, and diminution of the intensity of the heart sounds within the first minutes of the massage. Shortly after the maneuver some patients became tranquil and could lie supine. At first no other therapy was used, but later morphine and/or digitalis were given to those patients who seemed to need such a medicament. Amobarbital was also given to very hypertensive patients. The massage, however, appeared to do more good than the drugs. In general the beneficial effect of the massage becomes manifest a few seconds after it is started. A great advantage of the procedure is that the physician can control the intensity of the changes of cardiac frequency and blood pressure. In some patients arterial hypotension was induced in 30 minutes, and it is believed that this response could be maintained as long as the massage was used. No accidents occurred in the author's series of patients, but the massage should always be gentle.

The procedure failed to control the condition in two patients with auricular fibrillation and three with aortic insufficiency. In these conditions the massage has proved to be generally ineffective. In one patient with auricular flutter the treatment was successful. In two patients with pulmonary edema, mitral stenosis, and hypertension it averted the crisis. In patients with acute failure associated with arterial hypotension the procedure is contraindicated. The fall in blood pressure and the decrease in cardiac work that are thought to follow the peripheral vasodilatation induced by massage have been achieved by some physicians through ganglion-blocking agents, but the difficulty in controlling the results and the danger of causing too great a drop in blood pressure make their use hazardous. This treatment seems also to benefit patients with angina pectoris and even those with coronary occlusion. Prolonged massage of the carotid sinus shortens the duration of the fatigue in cardiac patients undergoing physical effort tests.

UNITED KINGDOM

Cortisone in Chronic Asthma.—The subcommittee on Clinical Trials in Asthma of the Medical Research Committee has issued a report of a controlled trial of the effects of cortisone in the treatment of chronic asthma and status asthmaticus. The trial on chronic asthma was carried out in six centers in the United Kingdom, in which 96 patients received either cortisone or placebo tablets. Those included in the trial were between 40 and 60 years of age, had a history of asthma of not less than three months' duration, and had had no complete remission of more than two weeks in the preceding three months. Patients with severe bronchopulmonary infection or a history of cardiac failure or tuberculosis were excluded from the trial. Each patient treated with cortisone received 300 mg. the first day of the trial, 200 mg. on the second and third days, and 100 mg. daily for the next four days; subsequently the dose was adjusted according to the requirements of the patient. All patients were treated for 24 weeks and followed up for a further 12 weeks, during which an attempt was made to withdraw the cortisone. In addition, each patient received any antispasmodic therapy considered necessary. The patients' condition was evaluated before and after treatment by physical examination, exercise tolerance, ability to work, and vital capacity. At first, slight but definite benefits were observed in the patients treated with cortisone, particularly diminution of rhonchi and increased exercise tolerance during the first eight weeks of treatment. By the end of 24 weeks and during the three months' follow-up study, the control patients gained ground, with the result that at the end of this period there was little difference between the two groups. The use of cortisone showed no advantage in enabling those to work who were initially unable to do so. The changes in vital capacity showed wide and similar variations in both groups. The general impression was that 23 of the 49 patients treated with cortisone were improved as compared with 12 of the 47 patients receiving the placebo.

The 32 patients included in the trial of the effects of cortisone in the treatment of status asthmaticus were all more than 14 years of age, had had at least one previous severe attack of asthma, and had not received any cortisone previously. All were admitted to the hospital and given what was the standard treatment in that hospital (e. g. epinephrine isoproterenol sulfate, aminophylline, and oxygen). Patients remaining in status asthmaticus after 24 hours of treatment were admitted to the trial. On the first day 350 mg. of cortisone was given in divided doses, on the second day 200 mg., then the dosage was reduced by 25 mg. daily until the 10th day, when no cortisone or placebo tablets were given. The total amount of cortisone administered was 1.25 gm. Clinical evaluation was based on a determination of the degree of bronchial obstruction present, using five arbitrarily defined clinical grades, and on temperature, respirations, and pulse rate. Details were also noted of antispasmodics used. The patients in the group treated with cortisone, without doubt, fared better than those in the control group. By the fourth day of treatment, 10 of the 15 patients treated with cortisone no longer had disabling bronchial obstruction, whereas only 4 of the 17 patients in the control group were as well as these patients. This difference between the two groups was maintained to the end of the period of treatment. Observation of the patients for three months after the trial showed that those in both groups reverted to their usual asthmatic condition. In the opinion of the committee, unless the patient is exhausted and dehydrated, cortisone should be used only when other methods used for 24 hours have failed.

"Prescribers' Notes."—The current issue of *Prescribers' Notes* sent to physicians in the National Health Service warns against the dangers of the indiscriminate use of erythromycin. It states that, because of the development of resistance of micrococci to the drug, it should be used only when the organisms have become resistant to penicillin and other antibiotics, and not as the first line of defense. It should not be used for chronic or trivial conditions and when the bacterial cause of an infection is not known. Attention is also drawn to the misuse of cortisone in the treatment of rheumatoid arthritis. The subcommittee of the Empire Rheumatism Council is quoted as finding no significant difference, after one year's treatment, between the two similar groups of patients, one treated with aspirin and the other with cortisone. *Lancet,* commenting on this report, notes: "Meanwhile the evidence from this and earlier trials raises the question whether cortisone, with its acknowledged dangers, is ever indicated in rheumatoid arthritis." Economy in prescribing is urged. The prices of various analgesics are compared with that of aspirin. Panadol (N-acetyl-p-aminophenol), which has the same analgesic action as acetophenetidin, costs three times as much as aspirin. One proprietary preparation of codeine compound is, on the other hand, only a few cents more a pack than the patented preparation. Figures are cited showing the large increase in the prescribing of proprietary preparations. In 1950, of the total number of prescriptions issued, 18% were for proprietary preparations; in 1955, 36% were.

Dangers of Myelography.—The dangers to the patient of myelography are pointed out by Davies (*Lancet* 2:747, 1956), who followed up 119 patients subjected to this procedure for periods of from 1 to 15 years. All but one have received injections of iophendylate, and 70 patients had experienced abnormal reactions to the injection. Complaints included headache, nausea, vomiting, giddiness, an increase in the severity of the original neurological symptoms, meningism, cranial nerve palsy, nystagmus, retention of urine, pyrexia, and severe pain in the spine. Fourteen patients had chronic symptoms or disabilities persisting for a year or more. These included headache, cervical pain and stiffness, persistent backache, continuous pain and cramp in the legs, urinary incontinence, intercostal neuralgia, paresthesias, and intensification of the original symptoms. The contrast agent was detected in the subarachnoid spaces of the brain and spinal cord two years after myelography. This was confirmed postoperatively, radiologically, and at autopsy on those who died. Davies considers that myelography should never be performed unless absolutely necessary and that, if it is, as much of the contrast agent as possible should be removed after the examination.

Malignant Hypertension and Irradiation.—A case of malignant hypertension induced by the irradiation of one kidney is described by Levitt and Oram (*Brit. M. J.* 2:910, 1956). A man had his left testis removed for seminoma, and, since secondary deposits formed in the upper abdomen, he was given deep roentgen therapy (3,000 r) to the left renal region. Later his blood pressure rose from 150/90 mm. Hg to 215/130 mm. Hg, with corresponding hypertensive changes in the electrocardiogram, while ophthalmoscopy revealed retinopathy grade 3 to 4. The process suggested a relatively acute and recent condition. Radiography showed an enlarged left ventricle and a poorly functioning left kidney. The latter was eventually removed. The blood pressure fell and all symptoms disappeared after the nephrectomy. Within 10 months there was no retinopathy. The case is of interest in view of Goldblatt's researches and the role of unilateral renal disease in causing hypertension.

Effect of Cortisone.—The *British Medical Journal* (2:800, 1956) contains a report by Dr. T. Nicol and co-workers on animal experiments that indicate that cortisone lowers the body defenses by depressing the phagocytic activity of the reticuloendothelial system, the total and differential leukocyte counts in the blood, and the gamma globulin level in the serum. Its beneficial action in certain diseases is probably due to a similar mechanism whereby it depresses the inflammatory reaction of the patient and thus holds in check the cycle of pathological changes. This is well illustrated in the cases of tenosynovitis and iridocyclitis, in which the use of cortisone reduces the inflammatory response and prevents the formation of adhesions while the infecting organisms can be attacked therapeutically with antibiotics. It would seem desirable, whenever possible, to give cortisone locally rather than systemically, in order to limit the depression of the defense mechanisms.

Calling the Resident.—In July St. Thomas's Hospital installed a new magnetic system for quickly summoning residents from anywhere in the hospital. It replaces the bells formerly used and at a lower cost for installation and upkeep. The system is based on that used for transmitting simultaneous translations of speeches at international congresses. Each member of the staff on call is provided with a receiver, resembling somewhat the handle of a small ophthalmoscope, which is clipped into a pocket. Each receiver—up to 56 can be run on one circuit—responds only to a signal from the controlling transmitter given at its own frequency. The response is a low-tone "peep, peep." With slight modification, the receiver can be adapted to transmit the human voice, but at St. Thomas's a nonverbal signal is preferred. The adaptation has been highly successful and is described in the October issue of *Hospital* (London).

Health Service Aims.—The annual report of the Ministry of Health for 1955 states that high priority will be given to bringing existing hospitals to a satisfactory standard and to providing new accommodation as and where it is needed; to insuring that the mental health services receive a proper share of the new construction and other resources available; and to providing adequate care for older persons. The achievement of these objectives will be facilitated by the rapid curtailment in the need for special beds for patients with tuberculosis.

A Fluorine-Containing Anesthetic.—Fluothane is a new fluorine-containing anesthetic that is being developed here. Bryce-Smith and O'Brien (*Brit. M. J.* 2:969, 1956) state that it is noninflammable and nonexplosive in the presence of 50% oxygen, undecomposed by warm soda lime (unlike trichloroethylene), and nonirritating to the respiratory mucosa and that it produces rapid anesthesia with quick recovery unaccompanied by nausea or vomiting. They administered fluothane by the open drop method, with the use of an inhaler calibrated to deliver known concentrations of fluothane vapor in air. A 2 or 3% concentration of fluothane in air produced a satisfactory level of surgical anesthesia after light premedication with meperidine hydrochloride or Pantopon and induction with thiopental sodium. Among the undesirable effects of fluothane were bradycardia, hypotension (average 90 mm. Hg systolic), and respiratory depression independent of the rate and depth of anesthesia. Cyanosis was frequently seen unless respiration was assisted or oxygen added to the gas mixture. Respiration was usually smooth and quiet, and regular muscular relaxation was generally sufficient; but, as the number of upper abdominal operations in this series was restricted, further information on this is needed. Some patients were also given muscle relaxant drugs, but the use of these with fluothane sometimes resulted in a severe fall in blood pressure. Recovery from the anesthetic usually occurred within 10 minutes after the stopping of its administration. The greatest disadvantage of fluothane was the depression of respiration; this was sufficient to limit its use to trained hospital anesthetists.

Excessive Prescribing of Cortisone.—Dr. T. Wilson, addressing a local hospital management committee at Bridlington, Yorkshire, said physicians were wasting the public money by prescribing cortisone too lavishly to patients with rheumatoid arthritis. He said that when patients went to consultants they received as much as three or four months' supply of the drug, which is very expensive. On an average a three months' supply costs $50; in some cases patients were receiving as many as 500 tablets at a time, costing $150. As some patients stopped taking the drug after a time, this represented a great waste. Dr. Wilson urged economy in prescribing such expensive preparations. Smaller supplies could be prescribed and then renewed when necessary. He also referred to the overspending of $8,700 on drugs and dressings at a local hospital, where the monthly consumption of cortisone was $1,625 against an estimated requirement of $300. A 2-oz. tube of hydrocortisone ointment costing $20 was often given to hospital patients for use as if it were calamine cream.

Dangers of Frozen Eggs.—Dr. K. E. Hughes, director of Portsmouth public health laboratory, addressing a meeting of the Royal Society of Health, described the importation of frozen eggs without control of their processing or sterilization before use as a grave menace to health. He said that large quantities of foreign frozen eggs were imported into the United Kingdom and that many of the eggs contained Salmonella. He said that of the last 171 batches of eggs examined at Portsmouth 44% were infected. If an infected batch were put through a baking process that did not kill the organisms, infection could result. He also said that synthetic cream was dangerous and had been the cause of outbreaks of salmonellosis. Another health officer, Dr. S. Hewitt, said that many outbreaks of food poisoning go unreported.

New Surgical Dressing.—A new microporous film wound dressing has been developed by Scales and co-workers (*Brit. M. J.* 2:962, 1956) from polyvinyl chloride film, with the use of polypropylene sebacate as a plasticizer. The film is manufactured by incorporating a pore-forming ingredient, such as starch or salt, into the plastic mass before its extrusion as a sheet. The pore-forming agent is later removed, leaving a structure whose porosity depends on the number and size of the intercommunicating pores between the cavities. This film is permeable to water vapor but not to bacteria contained in an aqueous medium. Trials were made to compare the healing rate of minor injuries covered with the new dressing with that of a similar group of minor injuries protected with a standard water-proof occlusive dressing. The new dressing largely fulfills the properties of an ideal dressing, namely, a high porosity to water vapor, absorption of blood and exudate, exclusion of micro-organisms, and being unaffected by domestic or industrial fluids, noninflammable, easily sterilized, and capable of being sealed to the skin. The film has a porosity of 1,400 to 1,800 gm. of water vapor per square meter at 37 C when the relative humidity is 75%. One drawback of the new dressing is that it is adherent to the wound surface.

Dickens' Illnesses.—The medical history of Charles Dickens, who was a chronic invalid, is discussed by Dr. W. H. Bowen in his book "Charles Dickens and His Family," published by N. Heffer and Sons, Ltd., Cambridge, England. Dickens, who died at the age of 58, is said to have suffered from renal calculi, chronic renal disease, gout, anal fistula, and cerebral atheroma. These conditions were diagnosed in retrospect by Dr. Bowen from a study of letters and contemporary documents. The novelist consulted Sir Henry Thompson in 1867 about his toe; erysipelas over an inflamed bunion was the diagnosis. In 1869 the diagnosis of gout was considered, but this was dismissed by Syme of Edinburgh, who confirmed the diagnosis of an inflamed bunion. When the first symptoms of cerebral atherosclerosis appeared, Dickens consulted Sir Thomas Watson and the advisability of discontinuing his public readings arose. Dickens' readings of his works were extremely popular, and Sir Thomas Watson agreed that they might continue without detriment to his health.

A New Steroid.—A new steroid found in chloroform extracts of human urine and related to mineral metabolism was described by Prunty and co-workers (*Lancet* 2:925, 1956). As it was first detected in the urine of a patient named Wildego, it has been provisionally called wildegosterone. It is distinct from aldosterone and has been identified by its ultraviolet absorption spectrum after separation by chromatography. The new steroid has not been found in the urine of healthy persons on a normal diet but only in the urine of patients with edema and muscle weakness or in that of normal persons after the administration of potassium ions. In an investigation of adrenal function in 100 pregnant women, the excretion of wildegosterone was found to increase steadily as pregnancy progressed, both in normal women and in those with toxemia. The findings suggest that wildegosterone is related to the metabolism of water and electrolytes.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Factors Influencing Conversion of Chronic Atrial Fibrillation with Special Reference to Serum Quinidine Concentration. M. Sokolow and R. E. Ball. Circulation 14:568-583 (Oct.) 1956 [New York].

Conversion of chronic atrial fibrillation or flutter to sinus rhythm was attempted 214 times in 177 patients, 94 of whom had rheumatic heart disease, 38 coronary heart disease, 20 hypertensive cardiovascular disease, 10 thyrotoxic heart disease, 1 congenital heart disease, and 14 miscellaneous conditions. One hundred fifty-three of the attempts were successful, and 61 were failures. Eight of the 177 patients had chronic atrial flutter and 169 had atrial fibrillation. Successful conversion of atrial flutter to sinus rhythm with quinidine was achieved in five patients, and in the three others the attempt failed; successful conversion of atrial fibrillation to sinus rhythm was achieved in 125 of the 169 patients. Thus successful conversion was achieved in 74% of the total group, but the percentage varied depending on the causation, duration of the fibrillation, presence of cardiac failure, and, in the patients with rheumatic heart disease, the type of the valve lesion. Atrial fibrillation of more than six months' duration decreased the likelihood of conversion in both the rheumatic and nonrheumatic patients. The incidence of conversion can be as high as 95% in nonrheumatic patients with fibrillation of short duration and as low as 45% in patients with rheumatic mitral incompetence with fibrillation of more than a year's duration. In the group with rheumatic heart disease, the poorest results were obtained in patients with predominant mitral incompetence, even when the effects of duration and presence of cardiac failure were excluded. In patients with uncomplicated mitral stenosis or with predominant aortic valvular disease the rate of conversion was almost as high as that in the nonrheumatic group. The presence of cardiac failure decreased the likelihood of successful conversion. The presence of systemic emboli in the immediate or remote past did not interfere with successful conversion of atrial fibrillation.

The average serum quinidine concentration required for conversion was 6.1 mcg. per cubic centimeter This level was achieved with an average dose of 2.2 gm. daily. Eighty per cent of the successful conversions were accomplished with a daily dose of 3 gm. or less of quinidine. With increasing doses, the additional yield of conversions without toxicity requiring cessation of the drug was only 20%. Eighty-five per cent of the successful conversions occurred at serum concentrations of 8 mcg. per cubic centimeter or less. Myocardial toxicity was infrequent at serum concentrations of less than 6 mcg. per cubic centimeter, but progressively increased as the serum concentration exceeded this figure. Toxicity was not always correlated with high serum levels, since 7 instances of myocardial toxicity were observed in 429 observations at levels of less than 6 mcg. per cubic centimeter. Caution must, therefore, be exercised, even when serum concentrations are low or falling. Toxicity was related more closely to the serum quinidine concentration than to the daily dose of the drug. A wide individual variation in serum concentrations was observed in patients receiving the same dose of quinidine.

The use of quinidine in established atrial fibrillation should be considered a calculated risk, and the physician must weigh the potential benefits against the possible hazards. Caution and reconsideration of the total situation should be the rule when 3 gm. of quinidine per day does not effect conversion or when the serum concentration reaches 8 mcg. per cubic centimeter Control of therapy with knowledge of the serum quinidine concentration should decrease the risk by indicating the statistical likelihood of toxicity at increasing concentrations of the drug Relapses to atrial fibrillation occurred in 85% of patients who did not receive maintenance doses of quinidine, but in only 20% of those given a maintenance dose of 1.6 gm. per day or in whom the maintenance serum concentration was more than 60% of the peak conversion serum level. The changing patterns of the atrial arrhythmia with increasing doses of quinidine and progressive slowing of the atrial rate support the concept that atrial fibrillation, atrial flutter, and atrial tachycardia are different manifestations of an ectopic focus and that the electrocardiographic differences between the three arrhythmias are a function of the atrial rate (rate of discharge of the atrial ectopic focus)

Febrile Pseudorheumatic Types of Early Cancer. I. Aguilar Rodríguez. Rev. clín. españ. 61:370-374 (June 30) 1956 (In Spanish [Madrid, Spain].

Febrile pseudorheumatic types of early cancer are frequent. The symptoms consist of fever and arthralgia of the type of acute polyarticular rheumatism Pain involves the ankles, shoulders, knees, and wrist joints. It can be differentiated from polyneuritis and the local pain caused by cancer or from its metastases. The joints may be inflammed and even deformed The etiology of the febrile type is difficult to interpret. Fever is high and resistant to antipyretic treatment. Arthralgia does not respond to antirheumatic treatment. Roentgen examination of the involved joints shows no metastases. Thirty-six patients with the typical syndrome were observed. Nine representative cases are reported. There were neither clinical symptoms nor roentgen signs of cancer in any patient. The erythrocyte sedimentation rate was accelerated. Symptoms followed the typical pattern in all cases. They either progressed to the state of anorexia, asthenia, symptoms of general infection, loss of weight, and appearance of the tumor in a few weeks or a few months, or they subsided temporarily and reappeared to follow the same course. A diagnosis of cancer was made only by the appearance of the tumor, which was noted several weeks or a few months after the appearance of the febrile pseudorheumatic symptoms The tumor was located in the stomach in 22 patients, either in the liver or in the lung in 4 patients, in the rectum in 2, in the pancreas in 1, in the kidney and brain in 1, in the bladder in 1, and in the cecum in 1. These types of cancer constitute an adaptation syndrome (according to Selye). They are due to an imbalance of the suprarenal hormones from a stimulus of the suprarenal glands under effect of cancerogenic substances Cancer of these forms is highly malignant. It runs a rapid course to a fatal end.

Syndrome of Congenital Absence of the Spleen with Associated Cardiovascular and Gastroenteric Anomalies. M. J. Aguilar, H B Stephens and J. T. Crane. Circulation 14:520-531 (Oct.) 1956 [New York].

Twenty-seven cases of congenital absence of the spleen in infants were collected from the literature, and three recent additional cases in a 20-month-old white baby girl and in two Chinese infants aged 3 months and 5 days, respectively, with certain cardiovascular and gastrointestinal abnormalities are reported. The three infants died, and autopsies revealed a characteristic association of multiple congenital anomalies, such as septal defects, particularly communication through a common atrioventricular orifice, anomalous venous return to the heart, pulmonary stenosis or atresia, transposition of the great vessels, accessory lobes of the lungs, partial situs inversus of the abdominal viscera, and abnormal mesenteric attachments. A complete blood cell count was done in two of the patients and revealed certain abnormalities, such as the presence of target cells

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them and leukocytosis, which have also been reported by other workers, in addition to osmotic fragility, Howell-Jolly bodies, transient normoblastemia, and siderocytosis. Thus, these hematological findings should afford a reliable diagnostic aid in future cases of agenesis of the spleen.

The presence of agenesis of the spleen presents extremely valuable information to the cardiovascular surgeon, especially as the cardiac anomalies often follow a predictable pattern. Having found partial situs inversus of the abdominal viscera in a patient showing the hematological abnormalities cited above, one should then strongly suspect the associated congenital heart disease to be of the cor biloculare type with a common atrioventricular orifice, anomalous venous return to the heart, and pulmonary stenosis or atresia. Less frequently there will also be present abnormalities of the great vessels, such as transposition, truncus arteriosus, and a right-sided aortic arch. The occasional inconstancy of these and the other anomalies should be borne in mind, however, and definitive diagnostic studies, such as cardiac catheterization, should be carried out before surgical intervention. Evidence of impaired pulmonary blood flow occurred in 19 of the 27 cases collected from the literature; pulmonary atresia was present in 11 cases and pulmonary stenosis in 7. Consideration of a shunt operation to increase pulmonary blood flow may be entertained in the management of these cyanotic infants, but a diagnosis of agenesis of the spleen by hematological means coupled with a foreknowledge of the high constancy of the associated anomalies should lead to a more definitive approach and estimate of prognosis. In 20 of the 27 collected cases the patients died before they reached the age of one year.

Ebstein's Malformation: A Clinical and Laboratory Study. R. A. Kilby, J. W. DuShane, E. H. Wood and H. B. Burchell. Medicine 35:161-183 (Sept.) 1956 [Baltimore].

The authors describe nine cases of Ebstein's cardiac malformation in three men between the ages of 26 and 35 years, three boys between the ages of 7 months and 11 years, and three girls between the ages of 10 and 13 years who were admitted to the Mayo Clinic. Cyanosis was evident at birth or early in childhood and persisted in five patients. In one of two patients in whom cyanosis had been noted at birth, the sign disappeared permanently; it reappeared in the other at 8 years of age. In one patient, acral cyanosis had been noted after exertion or exposure to cold since the age of 5 years. Cardiac catherization was performed in all nine patients. Every patient had a right-to-left shunt at an atrial level, although minimal arterial desaturation was present in three patients. Five patients were thought to have peculiar, distally displaced but competent tricuspid valves. In two patients, tricuspid insufficiency was considered to be revealed by the presence of ventricular pressure pulses in the true right atrium. No gross abnormality in the position of a competent tricuspid valve could be shown in two patients. Somewhat increased atrial pressures were obtained in these two patients and the impression of an anomalous arrangement of the bicuspid leaflet was gained in one of them. Five of the patients are living and four died. Four patients underwent cardiac operations in an attempt to relieve the right-to-left shunt and to prevent the possible occurrence of cerebral abscesses and paradoxic emboli. One patient has been greatly improved and at present is working part time. The three others died, one during the induction of anesthesia and two during the immediate postoperative period. One patient died of cardiac failure two years after the initial examination. Autopsy in two patients revealed no obvious cause of death besides Ebstein's cardiac malformation in one in whom the diagnosis thus was confirmed; cerebral infarction was found in the other.

Seventy-one additional cases of Ebstein's cardiac malformation were collected from the literature. The findings in the 80 patients with this malformation indicate that considerable variation occurs in this pathological aberration with respect to its effect or function. Attention is drawn to the unusual course that the blood may follow in some patients, if it is to fill the right ventricular chamber. It is theorized that in some patients such filling may be prevented because the valve is pushed against the free wall of the right ventricle by blood in the atrial portion of the right ventricle. Most cases of Ebstein's disease are associated with a typical clinical picture. This picture is complete if the electrocardiogram shows a tracing characterized mainly by the pattern simulating right bundle-branch block, although the R wave from the right precordium is of low voltage and of a multiphasic type. Auscultation reveals a double murmur in the left parasternal region, perhaps with a loud third heart sound, and the roentgenogram shows moderate cardiac enlargement with decreased pulmonary vascular markings. The phonocardiogram may be sufficiently characteristic to be of diagnostic importance.

An Association Between Blood Group A and Pernicious Anaemia: A Collective Series from a Number of Centres. I. Aird, H. H. Bentall, J. Bingham and others. Brit. M. J. 2:723-724 (Sept. 29) 1956 [London, England].

For several years studies on pernicious anemia were carried out in various hospitals in London, Oxford, Cambridge, Sheffield, Newcastle, and Glasgow, and the ABO blood groups of the patients were determined. The composite total number of 1,114 patients with pernicious anemia included 490 who were of group O, 503 of group A, 86 of group B, and 35 of group AB. The combination of data from these hospitals has shown with fairly high significance that pernicious anemia is commoner in persons of group A than in persons of group O, and also perhaps, though the numbers are small, than in persons of group B. The greater incidence in group A appeared in both sexes.

ABO Blood Groups and Secretor Character in Duodenal Ulcer: Population and Sibship Studies. C. A. Clarke, J. W. Edwards, D. R. W. Haddock and others. Brit. M. J. 2:725-731 (Sept. 29) 1956 [London, England].

Two hundred ninety-three patients with duodenal ulcer and their sibships were studied in an attempt to ascertain whether there is an association between blood group O and duodenal ulcer as has been suggested by recent reports from several areas of Europe and the United States. The findings in these previous reports were obtained by comparing the blood groups of ulcer patients with those in a control series of persons without ulcer in the same area. Such controls can be unsatisfactory, in that a population of mixed origin may contain elements with a high incidence both of group O and of duodenal ulcer without the two being causally connected. For this reason the authors had unaffected sibs among the studied sibships act as controls who were not subject to this criticism.

The data obtained from the 293 duodenal ulcer sibships gave no evidence to support the hypothesis that a person belonging to group O is more likely to have a duodenal ulcer than are his group A, B, or AB sibs. This result could be regarded as evidence in support of the suggestion that the previously reported association between blood O group and duodenal ulcer was due to racial stratification within the populations concerned. There are, however, considerable objections to this explanation, and a second hypothesis that would explain the previously reported findings suggests that it is not the blood group of the person that increases the likelihood of ulceration but, at least in part, the blood group of the person's mother. The children of group O mothers will have a higher frequency of blood group O than that found in the general population, and, if a group O mother did predispose her children to ulcer irrespective of their blood groups, both affected and unaffected offspring would have the same high group O frequency. The numbers in the authors' study, however, were far too small for any definite conclusions that would have confirmed this hypothesis.

The ability to secrete ABO blood group antigens in body fluids is an inherited characteristic, and it seemed possible that secretors and nonsecretors might have different susceptibilities to duodenal ulcer. The secretor character in the saliva of 514 unrelated patients with duodenal ulcer was therefore studied and the results were compared with those of 491 controls from the general population. There was a significantly higher proportion of nonsecretors in the patients with duodenal ulcer (35%) than in the controls (24.2%). This difference was found in both males and females belonging to each of the ABO blood groups and in both macroscopically and radiologically diagnosed cases. These data suggest that in nonsecretor persons duodenal ulcer may be about 45% more likely to develop than in secretors. For the same reason as in the association between group O and duodenal ulcer, the secretor characteristic was tested in the sibships of 262 patients with duodenal ulcer, and the results in the 262 families suggested that the relationship between nonsecretion and duodenal ulcer may hold within families. The possibility that the ABO and Lewis antigens may confer some protection against duodenal ulcer by virtue of their mucoid character has been discussed.

Incidence of the Common Forms of Human Leukemia. B. MacMahon and D. Clark. Blood 11:871-881 (Oct.) 1956 [New York].

In an attempt to assemble data on all residents of the borough of Brooklyn in whom a diagnosis of leukemia was made in the period from 1943 to 1952, a total of 1,792 abstracts of hospital records and 1,830 death certificates were obtained that gave information on 1,709 patients. The mean population of Brooklyn over the same period was used to express incidences of the various forms of leukemia in relation to color, sex, and age.

The incidence of leukemia in white males and females was 71.3 and 57.7 per million per year respectively. Corresponding rates for Negroes were 46.5 and 30.6. The white-Negro difference was decreased but not eliminated by standardization to allow for differences in the age distributions of the two populations. Sex ratios were lower for the acute forms of the disease than for the chronic forms, and, in both acute and chronic forms, for myeloid than for lymphatic cell types. No relationship of sex ratio to age at the time of the diagnosis or the initial white blood cell count was found. Each pathological variety of leukemia has its own distinct age incidence curve. The lymphatic forms appear to be more sharply associated with both extremes of age than do the myeloid varieties. That is, acute lymphocytic leukemia appears at a younger age than does acute granulocytic leukemia and the chronic lymphocytic form appears at an older average age than the chronic granulocytic variety.

The Present Status of the Diagnosis and Treatment of Syphilis. J. E. Vandow and N. Sobel. New York J. Med. 56:2796-2802 (Sept. 15) 1956 [New York].

The diagnosis of syphilis has become increasingly difficult because of the frequency of biologic false-positive serologic reactions. Considerable progress is being made toward solving this problem as a result of the recent development of a number of new laboratory tests. Four new serologic procedures and their application to the diagnosis of syphilis are discussed. These are the Treponema pallidum immobilization, immune-adherence, agglutination, and complement-fixation tests. These new tests are additional diagnostic aids in special situations but have not replaced the standard serologic test for routine use. In a study of 191 patients with positive blood tests suspected to be biologic false-positive reactions, the immobilization test was reactive in 66 (34.6%), indicating that syphilis was actually the cause of the positive serologic test in one-third of the cases. The clinical impression of a biologic false-positive reaction was confirmed in the remaining 125 patients. In patients in whom the diagnosis of latent syphilis was suggested by clinical data, this was verified in only half the patients. The schedules of treatment with penicillin and other antibiotics used by the New York City Health Department are described.

Obesity and Diabetes Mellitus. R. Murphy. J. Michigan M. Soc. 55:1209-1210 (Oct.) 1956 [St. Paul].

The obese diabetic patient differs in many respects from the thin diabetic patient. Most obese diabetic persons are adult. The onset of the disease usually occurs after the age of 40 years and the patients are predominantly women. Diabetes in the obese patient is usually stable in type. Often it can be controlled by reduction of dietary carbohydrates and the control maintained by reduction in weight. Ketosis rarely occurs, and, in those who require insulin, hypoglycemic episodes are not common. The apparent toleration of hyperglycemia has led to the mistaken idea that diabetes in the obese patient is "mild" and need not be given as serious consideration as diabetes in the thin individual. Actually, the obese diabetic patient is heir to all the serious complications, but usually there is not an absolute deficiency of insulin.

The antidiabetic sulfonamide drug carbutamide seems to be most effective in diabetic patients who still possess the capacity to secrete insulin, that is, in the obese group. The response to antidiabetic sulfonamides can be determined by estimating the blood sugar level before and four to six hours after a test dose of 2.5 or 3 gm. If the patient responds to the medicament by a significant fall in blood sugar, then a trial of treatment may be given, using 2.5 gm. on the first day, 1.5 gm. on the second day, and 1 gm. daily thereafter. If carbutamide is used, it is essential to remember the following points: 1. The medicament is an adjunct to, not a substitute for, dietary management. 2. The patient must be kept under close observation for the development of toxic side-effects, such as rash, leukopenia, crystalluria, and possibly jaundice. 3. Insulin must be used in the presence of infection, surgical operations, and especially with ketosis. 4. The antidiabetic sulfonamides are not an easy way out in the treatment of diabetes; they should be used with caution and only in patients who have proved that they are dependable.

SURGERY

Results of Mitral Commissurotomy for Mitral Stenosis: An Analysis of 48 Patients Followed from One to Five Years. J. L. Lee Jr., R. R. Shaw and D. L. Paulson. Texas J. Med. 52:729-734 (Oct.) 1956 [Austin, Texas].

Of 48 patients with mitral stenosis followed for from one to five years after mitral commissurotomy, 47 were in class 3 or class 4 before operation, or in terms of symptoms they were progressively incapacitated or were in congestive failure. There was one operative death and eight late deaths due to progressive heart disease. Of the patients who survived, 36 either had excellent results or were definitely improved, whereas 2 were not improved. Although these results are good and compare favorably with those reported in other larger series, the author feels that, through the use of newer diagnostic measures, chiefly cardiac catheterization of the right and left side, it will be possible to improve the results by eliminating from the operative group cases that are not suitable for operation.

Aneurysm of Thoracoabdominal Aorta Involving the Celiac, Superior Mesenteric, and Renal Arteries: Report of Four Cases Treated by Resection and Homograft Replacement. M. E. DeBakey, O. Creech Jr. and G. C. Morris Jr. Ann. Surg. 144:549-573 (Oct.) 1956 [Philadelphia].

DeBakey and associates report observations on four patients with extensive thoracoabdominal aneurysm of the aorta treated by resection and homograft replacement. In all of these patients the aneurysm extended from the lower descending thoracic aorta to the lower abdominal aorta and involved the celiac, superior mesenteric, and one or both renal arteries. The operative procedure consisted in excision of the aneurysm and replacement with an aortic homograft with restoration of continuity to the celiac axis and superior mesenteric arteries in all as well as to both renal arteries in two, and to one of the renal arteries in the other two patients. The most important consideration in extirpation of aneurysms of this type arises from the potential ischemic damage to such vital organs as the kidneys, liver, and gastrointestinal tract as a consequence of temporary arrest of circulation during the procedure. Two methods are available to overcome this problem, namely hypothermia and the use of a temporary shunt to conduct blood around the occluded segment.

Hypothermia was used in the first patient, but he died of renal failure one week after the operation. The superior mesenteric and both renal arteries were occluded for 105 minutes and the celiac artery for 120 minutes. Temporary shunts were employed in the other three patients. The successful results obtained in these patients emphasize the importance of performing the procedure in such a manner as to minimize the period of ischemia to the vital structures. The period of occlusion of the renal arteries ranged from 15 to 46 minutes. Serial renal function studies in these patients revealed a characteristic pattern of depression of function, as reflected by increase in the blood urea nitrogen level and reduction in renal blood flow and glomerular filtration rate during the first 4 or 5 days after operation with progressive return to normal during the subsequent 10 days to two weeks. The period of occlusion of the celiac artery in these cases ranged from 44 to 116 minutes. Studies of hepatic function revealed no significant alterations. The period of arrest of circulation through the superior mesenteric artery varied from 36 to 102 minutes, and no significant disturbances in gastrointestinal function were observed.

Cystic Medial Necrosis as a Cause of Localized Aortic Aneurysms Amenable to Surgical Treatment. H. T. Bahnson and A. R. Nelson. Ann. Surg. 144:519-528 (Oct.) 1956 [Philadelphia].

A patient with cystic medionecrosis of the aorta was a 39-year-old Negro male with a progressively enlarging fusiform aneurysm of the ascending aorta, who had been followed over an eight-year period. Chronic congestive heart failure occurred that appeared to be rapidly and irreversibly progressive. In the absence of syphilis and infection a diagnosis of cystic medionecrosis was made, and this was confirmed by examination of the surgical specimen. Approximately half the aneurysm of the ascending aorta was excised and the remaining vessel wrapped with a nylon binder. Slight constriction of the first portion of the aorta apparently relieved the previously incapacitating aortic insufficiency. Initially improved, he died suddenly five months later, his death being attributed to a myocardial infarction, although the visible infarct was a healing one. In the past year the authors have seen three additional patients with similar involvement of the ascending aorta and one of the distal aortic arch, all with histological evidence of cystic medionecrosis. This pathological condition, called Erdheim's cystic medionecrosis, has been previously recognized as a cause of aortic weakness and has been demonstrated in four groups of patients: 1. It is often present in cases of dissecting aneurysm and is thought to be the principal cause of dissection in young individuals. 2. It is commonly described as the cause of aortic weakness in cases of spontaneous rupture of the aorta. 3. It is one of the characteristic features of Marfan's syndrome (with, in addition, arachnodactyly, dislocated lenses, and a generalized defect in ground substance). 4. It is sometimes seen in slight degree in otherwise normal aortas.

The authors emphasize the production of localized aneurysms by cystic medial necrosis. Such aneurysms have been seen principally in middle-aged patients in the ascending aorta but also at the distal end of the aortic arch. In the latter location the lesion may be treated by excision and aortic anastomosis, possibly with an interposed graft. When the ascending aorta is involved the aortic valve may become incompetent as a result of dilatation of the valve ring. The aneurysm as well as the valvular incompetence have been relieved by excision of part of the circumference of the aorta and restoration of an essentially normal diameter. The structurally weakened aortic wall was reinforced with a nylon binder. The condition can be recognized clinically and should be treated before great dilatation of the aorta, aortic dissection, or chronic heart failure occur.

The Surgical Management of Achalasia of the Esophagus. H. R. Hawthorne, A. S. Frobese and P. Nemir Jr. Ann. Surg. 144:653-669 (Oct.) 1956 [Philadelphia].

The authors review observations on 35 patients with achalasia of the esophagus who were treated by a modified Heller operation, an extramucosal esophagocardiomyotomy. Follow-up studies including roentgen examinations and manometric studies of esophageal motility revealed that an excellent result was obtained in four-fifths of the group. Recurrent dysphagia, appearance of substernal pain, or gastrointestinal bleeding occurred in 21%. Regurgitation of gastric contents into the esophagus was demonstrated in each patient in whom the surgical result was unsatisfactory. The addition of pyloromyotomy failed to protect these patients from regurgitant esophagitis. The presence of esophagitis preoperatively or the presence of duodenal ulcer disease appears to affect the result adversely. The physiological basis for the good results is not clear. It seems that benefit is obtained by breaking the "circus movement" and eliminating spasm at the distal end of the esophagus rather than by any change in the esophageal motility.

Adrenalectomy for Control of Cancer of the Breast. M. H. Rabwin, D. H. Rosenblum, B. Simkin and others. California Med. 85:213-219 (Oct.) 1956 [San Francisco].

Combined oophorectomy and adrenalectomy was performed in 10 patients with metastatic carcinoma of the breast. All had metastasis to soft tissue and/or bone associated with active progressive symptoms due to the metastatic lesions. The metastatic lesions could be objectively demonstrated in every case. There was no selection as to age, pathological type of tumor, type of metastasis, or previous therapy. Eight of the 10 patients had had varying amounts of hormonal and x-ray therapy previously, despite which the disease was still progressing. Particular attention was given to the preoperative and postoperative management. In addition to the routine preoperative tests, serum electrolytes, calcium metabolism, and hormonal production were investigated, and a roentgenologic search for metastases was made. Preoperative preparation with cortisone given intramuscularly was frequently sufficient to carry the patient through the surgical procedures without incident or need of further steroid therapy.

In all but one of the patients the operation was done in two stages, bilateral oophorectomy and left adrenalectomy in the first stage and right adrenalectomy a week or 10 days later. In one instance the entire procedure was done in one stage. When the patient is in reasonably good condition, the one-stage procedure can be done safely. There were no surgical deaths. After the operation all of the patients were satisfactorily maintained by the oral administration of 50 mg. of cortisone daily in divided doses. Desoxycorticosterone was given sublingually in doses of 2 mg. daily. Remissions were achieved in 3 of the 10 patients; the other 7 died of metastatic disease. Cerebral or hepatic metastasis contraindicates adrenalectomy for metastatic cancer of the breast. Five of the seven patients not benefited by the operation had either cerebral or hepatic metastasis. The best candidates for adrenalectomy are premenopausal women who have previously had a clinical remission after oophorectomy and who have subsequently relapsed. The indications for adrenalectomy in the postmenopausal woman are not clear.

Needle Biopsy of the Parietal Pleura. P. Heller, W. F. Kellow and B. Chomet. New England J. Med. 255:684-690 (Oct. 11) 1956 [Boston].

The authors describe needle biopsy of the parietal pleura, which they carried out in 20 patients. The site of the biopsy is selected fluoroscopically. The skin is prepared for pleural aspiration. A no. 22 anesthesia needle is used for measurement of the thickness of the chest wall and the parietal pleura, this needle being slowly introduced until fluid is aspirated. After the anesthesia needle is withdrawn a Vim-Silverman needle is inserted a shorter distance, leaving room for protrusion of the split needle after the obturator has been removed. The split needle is advanced and is rapidly rotated in a manner similar to the technique of liver biopsy, and then the entire unit is speedily withdrawn. The specimen is usually small, often measuring about 3 mm., and may include intercostal muscle. Only one of the specimens thus far has included pulmonary tissue, and in this case there was no evidence of an adverse effect to the patient. The only complication of 22 needle biopsies in 20 patients has been a small hemothorax in one. This was recognized by an increase in the pleural effusion after biopsy and did not cause any serious consequence. A chest roentgenogram should be obtained 24 hours after biopsy.

The histological diagnosis was caseating granuloma in five cases, malignant neoplasm in four, and nonspecific fibrosis in nine; in 2 an insufficient specimen was obtained. Analysis of the five patients in whom a caseating granuloma was found demonstrates the common clinical problem with which a physician is often faced when he has only the traditional methods of examination available. The diagnosis of tuberculosis was suspected in only three of these patients before the biopsy, and neoplastic disease appeared to be more likely in the other two. The tuberculin test was positive in all five patients, whereas the histoplasmin, coccidioidin, and blastomycin tests were negative. Culture of the pleural fluid in three of these five patients remained negative, and in the other two patients the cultures were positive, but not until several weeks after the biopsy results had been obtained. Case reports demonstrate the usefulness of this procedure in patients with tuberculous pleural effusion. Needle biopsy of the parietal pleura may contribute significantly to the early detection of the cause of a pleural effusion. Although the specimens obtained were subjected only to histological examination, they should also be suitable for bacteriological studies.

Pleural Biopsy. I. A. Breckler, M. C. Hoffman, H. E. Hill and others. New England J. Med. 255:690-694 (Oct. 11) 1956 [Boston].

The Pulmonary Disease Center with which the authors are connected serves as a diagnostic center for chest problems in Air Force personnel. They subjected 16 patients with pleural effusion or blunted costophrenic angle to open pleural biopsy, which does not necessitate rib resection. The first five patients with pleural effusion were examined by needle and open biopsy techniques under local anesthesia. The open biopsy was no more difficult, and tissue specimens obtained were so superior that the needle biopsy method was abandoned. The pleura is approached through an intercostal incision, which is carried through intercostal muscles and endothoracic fascia to the pleura. The pleura is cleaned by blunt dissection and the visible portion grasped with an Allis forceps and excised. Experience taught that the most consistent and easily accessible point where the parietal and visceral pleura are fused is through the seventh or eighth interspace in an anterolateral position on the involved side. In most cases fusion in this area occurs as early as six weeks from the onset of the effusion, but a free pleural space does not contraindicate the biopsy even though a pneumothorax may result. Immediate catheter suction is instituted, and the patient is usually not even aware that his lung has collapsed. There were no other complications.

A portion of the fresh specimen was taken for bacteriological study, and the remaining tissue was fixed and stained. In 9 of 10 patients in whom tuberculous pleural effusion was suspected the diagnosis was confirmed by the finding in the specimen of typical histological evidence of tuberculosis. Acid-fast bacilli were demonstrated in five of the nine specimens. The 10th patient had a normal pleura on biopsy after four months of antituberculous chemotherapy; cavitation of the left lung, with a positive sputum, developed six months later. In this case the previously blunted costophrenic angle had disappeared, leaving a sharp angle at the time of biopsy. These 10 patients all had positive tuberculin reactions. In two patients with intrathoracic neoplasm a diagnosis was made or substantiated by pleural biopsy when other diagnostic techniques had failed. In two patients with streptococcic pneumonia with effusion, one patient with a residual hemothorax, and one patient with collagen disease, the pleural biopsy showed no specific changes.

The Surgical Significance of Ulcerative Colitis in Infants and Children. I. A. Meeker Jr. and P. Goff. West. J. Surg. 64:545-551 (Oct.) 1956 [Portland, Ore.].

Twenty-five infants and children with intermittent or chronic unremitting ulcerative colitis were admitted to the Children's Hospital, Los Angeles, between 1945 and 1955. The onset of the disease in most of the patients occurred at the time of some major emotional disturbance and was precipitated by separation or divorce of the parents, death of a close relative, environmental changes such as scout camp, summer camp, or relocation of the home, and extreme anxiety and concern over pubertal sex problems, such as masturbation. Chronic or recurring diarrhea and cramp-like abdominal pain caused weight loss, dehydration, and anemia, which made hospitalization necessary. The entire abdomen was rather tender and sensitive to palpation during the acute phase of the disease, and hyperactive intestinal sounds were frequently heard by auscultation. After control of the acute illness by medical measures, a proctoscopic examination was carried out with the aid of general anesthesia. The mucous membrane often appeared granular and grey and bled easily when touched, but an obvious ulcer crater was found only rarely. A considerable amount of mucus or mucopurulent exudate was noted occasionally in the rectal ampulla. Characteristic changes in the colon were revealed by roentgenologic examination in patients in whom the disease process had persisted for a prolonged period; there was loss of haustrations, and the colon had become foreshortened and tubular with loss of the redundant sigmoid loops; ulcerations were outlined by the barium column.

Two boys and six girls had a relatively mild form of the disease with two or three attacks of intermittent ulcerative colitis, but between these exacerbations they have had normally formed stools. The average age of these patients at the onset of the disease was 7 years. They were followed closely and were given continuous pediatric and psychiatric care with very gratifying results. None of these children was operated on and none went on to the more chronic unremitting form of the disease. The remaining 17 children, 8 girls and 9 boys, had the chronic unremitting form of ulcerative colitis. The average age of these patients at the onset of the disease was 8.8 years and the average duration of the disease was 5.4 years. All had either liquid or semisolid stools. Thirteen have been sustained successfully to date by medical management including administration of antibiotics to control infection, liberal use of whole blood transfusions to combat anemia and hemorrhage, and, in case of failure of these measures, judicious use of corticotropin or cortisone in doses appropriate to the age of the patient. Of the remaining four patients, one boy with the onset of his disease at 10 years of age who had ileostomy alone performed six years later died of carcinoma of the colon at the age of 21, after an interval of almost 11 years. The other three children have permanent ileostomies and have had total colectomy and abdominoperineal resection of the rectum, carried out in one stage in two of the patients. Each of these three children had irreversible x-ray changes in the colon, systemic manifestations of arthralgia, subcutaneous abscesses, and rectal fistula formation necessitating radical surgical intervention. All three are alive and well, have gained weight, and have been able to pursue far more normal healthy lives than was possible before surgery. Emergency ileostomy was rarely necessary, and more radical surgical procedure could be performed to cure patients with long-standing disease. Only those patients who have had their disease for more than 10 years without remission should be urged to undergo definitive surgery regardless of any psychogenic considerations.

Total Colectomy and Abdominoperineal Resection (Pan-Colectomy) in One Stage. M. M. Ravitch. Ann. Surg. 144:758-767 (Oct.) 1956 [Philadelphia].

In the Baltimore City Hospitals and the Johns Hopkins University Hospital pancolectomy (one-stage total colectomy and abdominoperineal resection of the rectum) is the preferred procedure for patients requiring operation for ulcerative colitis. Patients with polypoid adenomatosis of the colon are not denied operation because of advanced age or overriding additional disease. The indications for total colectomy and abdominoperineal resection are given. Anal ileostomy should be added in all cases of colectomy for polyposis and in suitable instances of colectomy for ulcerative colitis. The less profoundly ill patients will tolerate the entire one-stage procedure without difficulty and will be spared the risk of additional anesthesia, incision, and operative procedure. The more profoundly ill will derive sufficient benefit from the ablation of the diseased intestine to compensate for the moderate increase in magnitude of the operative procedure and will be spared the dangers of sepsis or hemorrhage attendant upon retention of the diseased rectum in ulcerative colitis.

The Use of Cortisone in Acute Diffuse Peritonitis. N. Molino and G. B. Xiume. Minerva med. 47:1993-1995 (June 23) 1956 (In Italian) [Turin, Italy].

Four patients operated on for severe acute diffuse peritonitis were treated with a combination of antibiotics and cortisone. Marked and speedy improvement in their general condition followed. The postoperative course of the disease was shortened and complete recovery followed. Deficiencies in the sodium and potassium metabolism and excretion did not occur in any of the patients. Cortisone had a marked antistress effect.

GYNECOLOGY & OBSTETRICS

Some Clinical Aspects of Factitial Proctitis. B. J. Kaplan. Connecticut M. J. 20:357-363 (May) 1956 [New Haven, Conn.].

Factitial proctitis occurred in 62 (38.36%) of 159 women between the ages of 20 and 78 years with gynecologic pelvic malignancy, for which they received irradiation therapy. One hundred forty-four (90.57%) of the 159 patients had carcinoma of the cervix and 15 had other pelvic malignancies. All patients with factitial proctitis had carcinoma of the cervix. One hundred nine patients were followed from the onset of the irradiation therapy for periods up to 21 months. The irradiation therapy consisted of deep x-ray therapy and administration of radioactive cobalt, followed by intracavitary radium application. Symptoms of factitial proctitis occurred in 43 of the 62 patients within a period of from three weeks to five or seven years after the initial irradiation therapy. Nineteen patients (30.65%) had no symptoms, although objective findings were present in the rectum or lower sigmoid. Symptoms consisted of bleeding, diarrhea, pain, constipation, abdominal cramps, rectal tenesmus, and excessive mucoid discharge. Proctoscopic examination revealed that telangectasia was present in all grades of proctitis. The earliest changes appeared as a mild or moderate erythema with some edema of the mucosa. The severity of the process may progress and lead to inflammation and eventually to ulceration of the intestine, usually on the midanterior rectal wall. An ulcer will occasionally continue to penetrate through the anterior rectal wall until a rectovaginal fistula results. Often it is impossible to tell whether one is dealing with infiltrating carcinoma or inflammatory tissue. Repeated proctoscopic examinations should be performed in all patients having undergone pelvic irradiation.

The 62 patients (82.86%) had mild proctitis and were treated topically with hydrocortisone. The course of therapy in most patients consisted of eight consecutive weeks of two daily rectal applications of 75 mg. of 2.5% hydrocortisone acetate. In some patients treatment was continued for 12 weeks. A pronounced proctoscopic improvement was noted after two or four weeks of treatment. Untreated lesions may heal within a period of from 12 to 24 months. Healing time was shortened by the treatment to three or four months. There is a definite possibility of intestinal perforation with topical application of hydrocortisone, and this possibility should be kept in mind. No other untoward reactions were observed.

Chronic Hypertension Following Pre-Eclamptic Toxemia: The Influence of Familial Hypertension on Its Causation. F. J. Browne and D. R. Sheumack. J. Obst. & Gynaec. Brit. Emp. 63:677-679 (Oct.) 1956 [London, England].

As a result of examining the blood pressures of parents and siblings of 100 primiparas who had preeclamptic toxemia and were followed up in the postnatal clinic, there seems to be sufficient evidence to suggest that those who belong to hypertensive families run a certain risk of developing residual hypertension immediately after the pregnancy in question. The evidence suggests that if the patient with preeclamptic toxemia does not belong to a hypertensive family, residual hypertension will not develop. It is probable that in patients in whom chronic hypertension develops the preeclamptic toxemia does not cause the hypertension but simply unmasks a familial tendency to hypertension and makes it develop earlier than it would otherwise have done.

Black Urine ("Black Water") After Use of Quinine During Pregnancy. U. Brost. Geburtsh. u. Frauenh. 16:698-706 (Aug.) 1956 (In German) [Stuttgart, Germany].

The first of the two patients presented was a 33-year-old woman who was given quinine to induce labor, her pregnancy having progressed beyond term. Since the first doses of quinine failed to induce labor, treatment with quinine was repeated on the following day. Petechial points appeared on the tongue, the oral mucous membranes, and on various parts of the body. The urine obtained by catheterization was black and contained many erythrocytes and a few leukocytes. Examination of the blood disclosed a decided thrombopenia, a prolonged coagulation time, and a decrease in the osmotic resistance of the erythrocytes. Fortunately, delivery did not start until after the hemorrhagic tendency had been corrected by large doses of vitamins C and K. Delivery was uneventful despite continued microhematuria. Subsequent inquiry revealed that a few weeks before the woman was hospitalized for the induction of labor she had taken a cold remedy known to contain quinine. She recalled that after that she developed "large blue spots" after only slight bruising. Some months later the woman reported that a sister of hers likewise had developed skin hemorrhages after taking a quinine preparation. The author deduced from this that a familial idiosyncrasy to quinine played a part in the development of the severe hemorrhagic reaction to quinine.

The second patient was an unmarried woman, aged 21, who took large doses (9 gm.) of a quinine preparation over a period of three days in order to induce an abortion. Here again the urine was black, and when the blood was examined the supernatant serum was red. Renal insufficiency developed, and the patient died from uremia and cardiovascular failure. The therapy of the quinine-induced hemoglobinuria should aim at restoring normal blood coagulation and at counteracting the increased permeability of the vascular walls.

Post-Eclamptic Vegetablism. C. W. F. Burnett. J. Obst. & Gynaec. Brit. Emp. 63:680-685 (Oct.) 1956 [London, England].

Burnett describes observations on a 26-year-old multipara in whom severe eclampsia progressed to a vegetative state that terminated in death after six weeks. Although patients with post-eclamptic psychosis and aphasia have been frequently described, only two similar cases of a vegetative existence following severe eclampsia appear in the literature. One of these two women died after six years of a vegetative existence and the other three months after delivery. The histological features of the brains are compared. The hypertension and prolonged anoxia that occur with severe eclampsia give rise to a hypertensive encephalopathy of profound degree, which, if the patient survives, produces areas of ischemic necrosis in both the grey and white matter that destroy the higher cerebral centers. In consequence of this damage the patient is reduced to a vegetative form of existence, from which there is no recovery. Such cases were rare in the past, as the severity of the eclamptic process necessary to produce such a severe encephalopathy usually killed the patient. With the improved treatment of eclampsia by means of hypotensive drugs and the salvage of patients who would have otherwise died, it may be expected that they will be encountered more frequently in the future. It is to be hoped that this threatened increase will be cancelled by a decreased incidence of eclampsia itself, for it is no therapeutic achievement to save the life of a patient at the cost of her living a decerebrate existence.

Bacteremia as a Cause of Obstetric Shock. J. G. Dumoulin and G. R. Steed. J. Obst. & Gynaec. Brit. Emp. 63:739-742 (Oct.) 1956 [London, England].

The histories of two women are cited to illustrate that severe obstetric shock can result from bacteremia acquired during labor. In both patients blood culture yielded Bacterium coli. The infection was acquired in the first patient during surgical induction of labor and in the second as the result of an infected blood transfusion. Both patients recovered. In view of the satisfactory response to vigorous treatment, this rare but dangerous condition should be borne in mind in cases of unexplained shock.

Analysis of Amniotic Fluid Cells for Diagnosis of Foetal Sex. L. Sachs, D. M. Serr and M. Danon. Brit. M. J. 2:795-798 (Oct. 6) 1956 [London, England].

An analysis of amniotic fluid cells was made in an attempt to diagnose the fetal sex in 40 cases in the ninth month and in 8 cases in the third, sixth, and seventh months of pregnancy. Amniotic fluid was obtained before delivery by puncture of the membranes and in the earlier months of pregnancy by abdominal puncture, except for the patient in the third month, in whom the amniotic fluid was obtained in the course of hysterectomy. A clear sex difference was found when the diagnosis was based both on the percentage of cells with a karyosome and on the percentage of cells with a karyosome at the nuclear membrane. The latter determination is to be recommended as a routine procedure, since it is easier to carry out.

In the 47 cases in the sixth, seventh, and ninth months of pregnancy there was a mean of 4% of cells with a karyosome at the nuclear membrane in males and a mean of 35% of such cells in females. The karyosome was also larger when found in cells of a female than in cells of a male. Three main types of epithelial cells, namely, basal, precornified or cornified, and keratinized cells, were observed in the amniotic fluid. Of these, the basal and precornified cells proved to be most suitable for the diagnosis of sex.

Determinations of the percentage of cells in the amniotic fluid that are suitable for the diagnosis of sex gave a mean of 12% suitable cells for both males and females in the sixth, seventh, and ninth months of pregnancy. In the one case in which the amniotic fluid was obtained in the course of hysterectomy at the end of the third month, 61% of the cells were suitable for the diagnosis; the diagnosis of female sex on the amniotic fluid cells was confirmed by a study of embryonic membranes. It was also possible to make a diagnosis on the cells in the fluid of an 8-week-old aborted embryo, and this was again confirmed by a study of embryonic membranes.

PEDIATRICS

Observations on the Etiology of Acute Laryngotracheobronchitis, Toronto, 1953-1954. E. A. Morgan, J. A. Turner, A. J. Rhodes and others. Canad. M. A. J. 75:638-641 (Oct. 15) 1956 [Toronto, Canada].

Fifty-two boys and 18 girls between the ages of 6 months and 10 years with acute laryngotracheobronchitis were admitted to the Tracheitis Unit of the Hospital for Sick Children in Toronto, Canada, between 1953 and 1954. All of them had two or more of the following symptoms: coryza, hoarseness, croupy cough, stridor, and dyspnea. Bronchoscopy was performed on 21 children, 8 of whom had supraglottic edema, 5 generalized edema, and 8 subglottic edema. Micrococcus (Staphylococcus) pyogenes was isolated from 28 of the 70 patients. Streptococcus pneumoniae was isolated from 23 patients. Hemophilus influenzae, type B, was found in one patient with the typical clinical picture associated with this infection. These findings confirmed earlier reports that there is no constant pattern of organisms in these cases. Twenty-one patients required tracheotomy. Inoculation of tracheal secretions into tissue cultures revealed agents cytopathogenic for tissue cultures of human embryo lung and monkey kidney cells in five cases, but only two of these agents could be propagated serially. The changes produced in monkey kidney cells took about six or eight days to appear in the case of the two strains that were successfully propagated.

The clinical and bacterological findings in these patients agreed with the aspect of the disease as described by Neffson in his monograph on acute laryngotracheobronchitis. The recognition of the severe case with poor air entry but only a muffled stridor is vitally important because tracheotomy is lifesaving. The results of modern treatment with cool, moist air, antibiotics, and tracheotomy were gratifying; only one of the 70 patients died.

Cortisone Therapy of Lye Burns of the Esophagus. E. S. Ray and D. L. Morgan. J. Pediat. 49:394-397 (Oct.) 1956 [St. Louis].

Since 1954 the authors have used cortisone and antimicrobial drugs in 11 children with lye burns of the esophagus. In view of the danger of serious mediastinal and pulmonary complications from cortisone therapy, the children were hospitalized during the period of cortisone administration. The ages of the 11 children ranged from 1 to 4 years, and 7 had severe and 4 had mild burns. Treatment with cortisone was started within 24 hours after the burn in 10 of the children. One child did not enter the hospital until the fourth day after the ingestion of the lye, at which time complete esophageal obstruction was present. After 3 days of steroid therapy this patient was able to swallow liquids, and at the end of 10 days she was able to take a general diet and a barium swallow was normal. However, a stricture of the esophagus developed in this child three months later that has required bougienage. This experience is further evidence of the ineffectiveness of steroid therapy when administration is delayed.

The authors favor the administration of olive oil and milk at frequent intervals to these patients. Diet is limited to liquid foods for three days and then puréed foods during the first two weeks. After that the child is given a general diet. Antimicrobial drugs (either a combination of streptomycin and penicillin or one of the broad-spectrum antibiotics) are given to all patients. Since most of these children have dysphagia, the drugs are given parenterally. Cortisone in doses of 25 mg. is given every six or eight hours; initially, during the period of dysphagia, it is given intramuscularly, later orally. The duration of cortisone therapy ranged from 7 to 30 days, the optimal duration being indefinite. The 10 children who received cortisone promptly had no evidence of stricture and have remained on a general diet during the period of follow-up (6 to 28 months). No complications resulted from the cortisone therapy.

Reserpine in Cerebral Palsy. R. D. Harris and E. H. Rowley. J. Pediat. 49:398-400 (Oct.) 1956 [St. Louis].

Following a pilot study with reserpine in 27 children with cerebral palsy ranging in age from 2 to 12 years, the authors began a controlled evaluation in 42 patients with cerebral palsy (including the initial 27). The 42 were divided into two groups. Group 1 was given 0.25 mg. of reserpine (elixir Serpasil) daily. Group 2 was given placebos. Group 1 received reserpine for a two-week period, after which they were changed to placebos and group 2 was then given reserpine for a two-week period. The two groups were as nearly identical in diagnosis as possible. The nursing personnel reported that all children receiving reserpine were happier and more cooperative and that there were fewer emotional upsets. In many instances the tension was reduced so that the children were better able to cooperate in the physiotherapy program. In some children in whom there had been fear of falling when walking, this fear was allayed. They tolerated their braces better and were able to manage them with greater ease. Children who were usually restless at night slept better, and the usual dose of sedative was lowered or completely withdrawn. There was an increase in appetite, and many showed weight gains.

Four illustrative case histories are presented. No significant changes in blood pressure were observed, although there was a slight reduction in cardiac rate. "Snuffy nose" was observed in some instances. Urticaria in a 4-year-old child subsided when reserpine was withdrawn and did not recur when treatment was resumed with a smaller dose (0.1 instead of 0.2 mg. twice daily). Drowsiness was sometimes noted, particularly with the larger doses of the drug. Reserpine was a helpful adjunct in a training program for children with cerebral palsy. The drug induced better cooperation, replaced sedations, and served as a tranquilizer in emotional states. It was especially beneficial in allaying tension in tension athetosis and in reduction of tremor in tremor athetosis. Dosage must be individualized, but 5 minims (0.02 mg.) of Serpasil elixir daily is adequate for maintenance therapy in small (25 to 30 lb. [11.3 to 13.6 kg]) children.

Clinical Features of Aseptic Meningitis Caused by Coxsackie-B Virus. D. L. McLeon, A. J. Beale, G. A. McNaughton and A. J. Rhodes. Lancet 2:701-703 (Oct. 6) 1956 [London, England].

The clinical features of 17 children with aseptic meningitis due to Coxsackie-B virus are described. They formed part of a series of 96 cases of aseptic meningitis diagnosed as "nonparalytic poliomyelitis" and studied at the Hospital for Sick Children in Toronto, Canada, from 1950 to 1955. Most of these children were hospitalized shortly after an abrupt onset of symptoms indicating meningeal irritation. Most were followed after discharge, when convalescent serums were collected. On admission, or as soon as possible after, stools, blood, and cerebrospinal fluid were collected for virus studies. The techniques of examination for viruses included the inoculation of suckling mice, monkeys, and monkey-kidney monolayer tissue cultures by standard methods. All except one of the 17 children (ranging in age from 4 to 11 years) yielded a Coxsackie-B virus that could be assigned to one of Dalldorf's antigenic types. Three patients excreted the same antigenic type of virus in stools and cerebrospinal fluid. Ten of the 12 patients who provided suitable samples of serum showed during convalescence a rise in antibody to the homologous Coxsackie virus isolated from stools.

All 17 children were adequately studied to exclude concurrent infection with poliomyelitis. One of the objects of this study was the simplification of the differential diagnosis, but this was not achieved. It did not prove possible, in the indivdual case, to distinguish between aseptic meningitis caused by Coxsackie-B, poliomyelitis, or "orphan" viruses. A knowledge of the prevalent disease in the community may suggest the likely diagnosis, a case of aseptic meningitis being likely to be due to Coxsackie-B, poliomyelitis, or mumps virus if pleurodynia, paralytic poliomyelitis, or mumps is present in the community. Even during epidemics of paralytic poliomyelitis, however, there is evidence that some cases of aseptic meningitis are not due to polomyelitis. It seems that about 20% of cases of aseptic meningitis in Ontario are caused by Coxsackie-B virus.

THERAPEUTICS

The Effect of ACTH and Cortisone on Gastroduodenal Ulcer: Experimental Study. F. P. Tinozzi and G. Dozio. Minerva chir. 11:699-703 (Aug. 15) 1956 (In Italian) [Turin, Italy].

The authors studied the effect of adrenal hormones on gastroduodenal ulcer, or, more particularly, the way in which these hormones are related to the occurrence of hemorrhage in ulcerous lesions of the gastroduodenal tract. Fifty guinea pigs with an average weight of 400 gm. were put on a monophagic diet low in vitamins. This diet produced in the animals lesions similar to gastroduodenal ulcer in man. The animals were divided into 5 groups of 10 guinea pigs each. The first group was kept as a control; it was put on a monophagic diet and received no hormones. The second group was treated with 6 mg. of corticotropin (ACTH) per day, beginning when the monophagic diet was started. The third group was treated with 6 mg. of corticotropin per day beginning 15 days after the monophagic diet was started. The animals of the fourth group received 6 mg. of cortisone per day beginning when the monophagic diet was started. Animals of the fifth group received 6 mg. of cortisone per day beginning 15 days after the monophagic diet was started.

Some of the guinea pigs in the first group were killed after the 13th or 15th day. Gastroduodenitis with hemorrhage was found, especially in the juxtapyloric region. The rest of the group died after from 45 to 55 days. Hemorrhagic gastroenteritis was present in all and gastroduodenal ulcers in 85%. The animals of the second group died after from 40 to 50 days. All of them had gastroenteritis, but none had ulcers. The animals of the third group presented after death hemorrhagic gastroduodenitis with ulcers, and three had a juxtapyloric perforated ulcer. Treatment with cortisone had no effect on the animals of the fourth and fifth groups, in which the findings were the same as in the first group.

Corticotropin and cortisone have no real ulcerogenic effect. Cortisone has no effect on gastroduodenal ulcers caused by a monophagic diet or on the occurrence of complications such as hemorrhage and perforation. Corticotropin given before the occurrence of a gastroduodenal ulcer has an inhibiting effect. If it is given after ulcers have developed, corticotropin causes complications.

Pellagra Caused by Isoniazid. R. J. Harrison and M. Feiwel. Brit. M. J. 2:852-854 (Oct. 13) 1956 [London, England].

Pellagra occurred in a 45-year-old woman who was given 300 mg. of isoniazid daily combined with 20 mg. of pyridoxine hydrochloride three times daily for multiple sclerosis of 20 years' duration. The patient's appetite had always been poor, and her intake of food was inadequate. During a particularly sunny summer, she had burning sensation in the hands and feet, and typical symmetrical pellagrous dermatitis developed on the hands and feet. Isoniazid was withdrawn. Her symptoms persisted for the next three weeks. She continued to take the same inadequate diet. The burning sensations in hands and feet did not let her sleep at night with her extremities covered. The latter symptoms were rapidly relieved when the patient was given 1 gm. of nicotinamide daily. The dermatitis improved, and within 18 days the skin appeared normal.

As the symptoms of pellagra appeared in the course of isoniazid therapy, there seemed to be a cause-and-effect relationship. Other clinical observations were collected from the literature that pointed to isoniazid being a contributory factor in producing pellagra when the patient was in a prepellagrous condition. These clinical findings suggest a possible metabolic antagonism between isoniazid and nicotinamide. Isoniazid bears an undoubted structural similarity to nicotinamide, which is an integral component of an essential oxidation-reduction coenzyme, i. e., diphosphopyridine nucleotide. Experimental work has shown that it is possible by enzyme action to cause an exchange of isoniazid for the nicotinamide portion of diphosphopyridine nucleotide; this points to a mechanism by which isoniazid might produce nicotinamide deficiency, but in experiments on the whole animal this has not yet been shown. The biological antagonism between isoniazid and pyridoxal is caused by a purely chemical reaction. The suggestion that the pellagra-producing effect of isoniazid depends on the patient's initial level of nicotinamide being low would cover the facts observed in the patient. An apparent relationship between isoniazid and a condition that is caused specifically by a nicotinamide deficiency points to an interference by isoniazid in nicotinamide metabolism; as an integral component of diphosphopyridine nucleotide, nicotinamide has its most important known metabolic function. The question remains whether these observations are a reflection in man of the mechanism by which the tubercle bacillus is inhibited by isoniazid.

Modification of Abnormal Serum Lipid Patterns in Atherosclerosis by Administration of Sitosterol. M. M. Best and C. H. Duncan. Ann. Int. Med. 45:614-622 (Oct.) 1956 [Lancaster, Pa.].

Sitosterol was administered to 24 patients for sufficient periods of time to evaluate its effect on serum cholesterol and other lipids. Several types of sitosterol suspensions were employed in early studies, but during the last 18 months a 20% suspension of predominantly beta sitosterols has been used. Six to 8 gm. of sitosterol were administered orally immediately before the ingestion of food, the usual total per day being 18 to 25 gm. With this treatment the mean decrease in serum cholesterol was 15.5% of the control level. The absence of toxic effects permits further study of the possible therapeutic value of sitosterol in human atherosclerosis.

PATHOLOGY

Cancer and Atherosclerosis. A. Elkeles. Brit. J. Cancer 10:247-250 (June) 1956 [London].

The incidence of calcified atheroma was investigated in patients with cancer and in controls over the age of 50 years. Radiography of the abdominal aorta has proved to be a valuable method for recognizing calcified atheroma during life. The abdominal aorta was radiographed in 1,116 patients over 50 years of age, comprising 416 cases of cancer of various organs and 700 controls. A low incidence of calcified atheroma was found in the cancer patients (18.7%) compared with the controls (36.7%). This difference is even more pronounced in the 71 to 80 age group, 28.4% against 71.9%. Calcified atheroma is rare in patients with carcinoma of the stomach and its incidence is low in those with carcinoma of the prostate and breast. The percentage of calcified atheroma in patients with cancer of the respiratory tract, however, does not differ from that of the control series. The hypothesis is proposed that the incidence of calcified atheroma is low in patients with cancers that are influenced by genetic factors or are hormone dependent. The incidence of calcified atheroma in patients with cancers predominately caused by exogenous carcinogenic agents does not differ from the control series. Persons with marked atherosclerosis are less likely to develop cancer of certain organs, e. g., of the stomach, breast, and prostate.

Patchy Myocardial Necrosis in Rabbits After Shock Doses of Histamine and Peptone. B. M. Herbertson. J. Path. & Bact. 72:137-141 (July) 1956 [Edinburgh, Scotland].

The experiments described demonstrate that histamine and peptone shocks may cause myocardial lesions in the rabbit identical with those found after anaphylactic shock or severe pulmonary embolism. In a previous discussion it was considered that in both the latter conditions myocardial ischemia accompanying distension of the right ventricle and atrium was the fundamental cause of the injury. As the alterations in the dynamics of the cardiovascular system produced the injections of histamine and peptone are similar to those found after anaphylactic shock and pulmonary embolism, it is probable that the mechanism of the lesions is also essentially the same.

Anticoagulant Therapy of Acute Myocardial Infarction: An Evaluation from Autopsy Data with Special Reference to Myocardial Rupture and Thromboembolic Complications. K. T. Lee and R. M. O'Neal. Am. J. Med. 21:555-559 (Oct.) 1956 [New York].

The effects of anticoagulant therapy have been evaluated from clinical and autopsy data in 500 patients with acute myocardial infarction who were treated and who died at Barnes Hospital in St. Louis between 1910 and 1954. One hundred seventy-four patients with myocardial infarction were admitted to and died at this hospital before the advent of the anticoagulant drugs, and of the 326 patients who were admitted after the introduction of anticoagulant therapy 108 were treated with anticoagulants and 218 were not. Intravascular thrombi complicating acute myocardial infarction were observed at autopsy in a significantly greater percentage of patients who did not receive anticoagulants than in patients who received adequate anticoagulant therapy within three days of the clinical onset of the infarction. This difference was apparent only when patients who died within three days of the clinical onset of the infarction were omitted from the comparison. This omission was justified because a much greater proportion of untreated than treated patients died within the first three days after onset of the infarction and because thrombi were less common in patients who died early in the illness. The incidence of thrombi was not affected if initiation of anticoagulant therapy was delayed more than three days after the clinical onset of the infarction. This finding suggests that anticoagulant therapy is not effective unless begun within three days of the clinical onset of the infarction.

Myocardial rupture occurred five times as frequently among anticoagulant-treated patients as among untreated patients in the same period. However, no significant over-all increase in myocardial rupture occurred between 1910 and 1954. The possibility exists that selection of patients receiving anticoagulant therapy accounted for the high incidence of rupture in the anticoagulant-treated patients, but no support for this explanation was found in the clinical histories. The incidence of myocardial rupture in untreated patients decreased slightly in the years between 1910 and 1954.

Hemopericardium without myocardial rupture was not significantly more frequently observed in patients treated with anticoagulants, and in none of the cases was the amount of blood considered sufficient to have caused the patient's death.

Malignant Paraganglioma of the Organ of Zuckerkandl. W. A. Haug and H. W. Baker. A. M. A. Arch. Path. 62:335-339 (Oct.) 1956 [Chicago].

The authors describe a case of malignant paraganglioma arising from the organ of Zuckerkandl (extra-adrenal abdominal chromaffin tissue) in a 60-year-old man complaining of low back pain of five months' duration. The pain was constant, aggravated by walking or coughing, and accompanied by numbness and weakness of the left lower extremity. A poorly defined, firm, deeply situated mass, measuring 8 by 10 cm., was palpable just above the angle formed by the spine and the left iliac crest. An attempt was made to obtain a biopsy specimen of this left lumbar mass by a posterior approach. A vascular, yellow-gray tumor was discovered lying within the quadratus lumborum muscle and invading the spine. Upon incision into the tumor profuse hemorrhage occurred. The tissue removed at operation was reported by the department of pathology as adenocarcinoma, possibly metastatic from the kidney or adrenal gland. The patient died six months after the operation.

On autopsy a bulging, lobulated fusiform mass was found partially covered by and invading the psoas muscle. It was located retroperitoneally, in the left paravertebral region, immediately adjacent to the bifurcation of the aorta. On microscopic examination, a high-power view of the tumor revealed large polygonal and elongated epithelial-like cells. A medium-power view of the tumor showed a syncytial pattern with sparse stroma. Gomori's chromaffin tissue stain on formalin-fixed tissue revealed cytoplasmic granules with positive chromaffin reaction On section, the enlarged liver was seen to be literally replaced by metastatic tumor nodules measuring from 1 mm. to 8 cm in size. These metastatic lesions appeared virtually identical with the parent tumor except that the cytoplasm of some cells appeared basophilic.

The site of the primary neoplasm, just lateral to the bifurcation of the abdominal aorta, suggests that it originated in the organ of Zuckerkandl. This tumor is the third malignant paraganglioma reported to have arisen in this location. Assay for epinephrine was not performed on the tissue obtained at operation or at autopsy. At no time during the hospitalization of the patient was hypertension or any other evidence of sympathetic overactivity observed. Although the two malignant paragangliomas of the organ of Zuckerkandl previously reported were both functioning tumors, most of the malignant paragangliomas arising in other sites, including the adrenal medulla, have shown no evidence of physiological activity.

Mitral Stenosis and Pulmonary Arteriosclerosis: Correlation of Pulmonary Arteriosclerosis, Right Ventricular Hypertrophy, and Thromboembolism in Autopsied Patients Who Died with Mitral Stenosis. W. A. Thomas, K. T. Lee, E. R. Rabin and R. M O'Neal. A. M. A. Arch. Path. 62:257-261 (Oct.) 1956 [Chicago]

The relations between pulmonary arteriosclerosis, right ventricular hypertrophy, and pulmonary thromboembolism were studied by examining autopsy records and microsections of the lung from 86 patients with mitral stenosis as a principal anatomic diagnosis. Right ventricular hypertrophy was taken as presumptive evidence that pulmonary hypertension had been present during life. For comparison, a "normal" (control) group of 50 patients with neither cardiac nor chronic pulmonary disease was selected by age from recently performed autopsies.

Thirty-five (41%) of the 86 patients with mitral stenosis had "moderate" or "advanced" arteriosclerosis of their small muscular pulmonary arteries, and none of the patients in the control group had more than "slight" pulmonary arteriosclerosis. There was no significant correlation between the presence of moderate or advanced pulmonary arteriosclerosis and the presence of right ventricular hypertrophy. This finding suggests that pulmonary hypertension is not an important factor in the production of arteriosclerosis of the small pulmonary arteries in patients with mitral stenosis. Evidence of obvious thromboembolism consisting of clearly recognizable organized or fresh thrombi or infarcts in the lungs was observed in 26 (30%) of the patients with mitral stenosis. Moderate or advanced pulmonary arteriosclerosis was present in 18 (70%) of the 26 patients with thromboembolic phenomena, and only 17 (28%) of the 60 patients without demonstrable thromboembolic phenomena had moderate or advanced pulmonary arteriosclerosis. Correlation between the presence of moderate or advanced pulmonary arteriosclerosis of the small pulmonary arteries and the presence of thromboembolic phenomena in the lungs thus was highly significant, suggesting that pulmonary thromboembolism is an important factor in the pathogenesis of pulmonary arteriosclerosis.

Although this study was concerned primarily with factors associated with pulmonary arteriosclerosis, it also has physiological implications that may be useful in explaining the benefit derived from mitral commissurotomy. The absence of a significant correlation between the presence of moderate or advanced pulmonary arteriosclerosis and right ventricular hypertrophy suggests that the degree of pulmonary arteriosclerosis observed in most patients with mitral stenosis is in itself insufficient to cause a significant increase in the pulmonary vascular resistance.

The Laurence-Moon-Biedl Syndrome. C. F. Ross, L. Crome and D. Y. Mackenzie. J. Path. & Bact. 72:161-172 (July) 1956 [Edinburgh, Scotland].

Clinical and postmortem studies on a 23-year-old man with the classical features of the Laurence-Moon-Biedl syndrome are presented. Laurence and Moon in 1866 reported on four patients in one family presenting a syndrome of obesity, hypogenitalism, mental deficiency, and retinitis pigmentosa. Subsequent reports added polydactyly to these abnormalities. Three hundred cases of this syndrome have been reported up to 1955. Autopsy studies have been reported in only 10 of these, and most of them were incomplete, the eye, for instance, having been examined in only two cases. The main alterations in the brain of the authors' patient were lipofuscin-like pigment in all of the nerve cells, which were somewhat reduced in number, patchy gliosis and slight demyelination of the optic tracts, and chiasma. The hypothalamus was essentially normal. The endocrine glands, in particular the pituitary, were normal. The eyes showed the changes of primary pigmentary degeneration. The kidneys were the seat of acute or chronic pyelonephritis. Death resulted from uremia. Uremia has been a frequent cause of death in the Laurence-Moon-Biedl syndrome. The type of renal disease is not constant; glomerulonephritis appears to be the commonest, but vascular disease, pyelonephritis, and hydronephrosis have all been described. The finding of a persistent fetal structure by Griffiths may be important, since his is the youngest patient examined and there was no superimposed renal disease. It is known that persistence of fetal structures predisposes to inflammations, and it would appear that in the Laurence-Moon-Biedl syndrome there is some obscure renal inferiority.

The Pathogenesis of Atheroma of the Coronary Arteries. C. I. Levene. J. Path. & Bact. 72:83-86 (July) 1956 [Edinburgh, Scotland].

The coronary arteries were examined histologically in 98 hearts, from all age groups, in order to determine the sequence in which deposition of fat, calcium, necrotic debris, and fibrin and vascularity of intima and media occur. The study confirmed that fibrin was the cause of the progressively enlarging fibrous intimal plaques. Other changes appeared to result from the failure of the superficial and deep zones of organisation to link up. Mensuration confirmed that localised intimal thickening is associated with thinning of the underlying media.

Osteoperiosteal Lesions of the Leg in the Course of Chronic Phlebopathy of the Lower Extremity. C. Mairano and P. M. Pasquero. Minerva chir. 11:541-546 (June 30) 1956 (In Italian) [Turin, Italy].

The authors studied osteoperiosteal lesions of the leg in the course of chronic phlebopathy of the lower extremity in 40 patients with varicositis and 30 patients with phlebitis. Damage to the bone was present in most cases. Superficial capillary circulation with altered local metabolism is the main cause for osteoperiosteal damage. Infection plays a secondary role. The altered physiochemical character of the interstitial fluid has a chronic irritating effect on the bone and periosteal cells. Hyperfunction or hypofunction follow according to the intensity of the stimulus of these cells. Hyperostosis and bone thickening follow in case of hyperfunction, osteoporosis in case of hypofunction. The periosteum does not remain immune to these processes, and its anatomy and function are affected by hypertrophy, involution, or degeneration.

Malignant Disease in Old Age. F. McKeown. Brit. J. Cancer 10:251-256 (June) 1956 [London].

In autopsy studies on 1,300 patients dying over the age of 70 years, heart disease ranked first and cancer second as a cause of death. Twenty-five per cent of patients in the series had malignant disease, and this proved fatal in 20%. Males were affected more frequently than females, confirming the findings of other workers on the sex incidence of carcinoma in later life. The incidence of tumors rose slightly in the eighth decade as compared with the seventh, but this was partly accounted for by the increasing incidence of carcinoma of the prostate with age. The commonest site for a malignant tumor was the large intestine, 22% of all tumors occurring in this situation. The second most common tumor was carcinoma of the prostate, accounting for 14% of all malignancies. Tumors of the stomach, lungs, esophagus, bladder, kidney, and pancreas followed in that frequency, and rare tumors were those of cervix and ovary, thyroid, and melanoma. Nevertheless, most sites were represented. Of all the malignant tumors discovered, 20% were incidental in that they were unsuspected and did not contribute materially to the death of the patient. This emphasizes the importance of complete postmortem examination as the only means of determining the true incidence of any tumor.

RADIOLOGY

The Use of Tantalum 182 in the Treatment of Early Bladder Carcinoma. P. J. van Miert and J. F. Fowler. Brit. J. Radiol. 29:508-512 (Sept.) 1956 [London, England].

The authors review the methods available for dealing with early carcinoma of the bladder and suggest that more attention should be paid to the possibilities offered by interstitial irradiation, particularly in the matter of uniform and adequate dosage to the lesion-bearing area and the reduction of dosage to unaffected areas of bladder to a minimum. They describe new methods of using radioactive tantalum (Ta ^{182}) wire to achieve these ends. Ta ^{182} wire is used in straight lengths with the terminal centimeter twisted on itself to form a loop for attachment of the withdrawal thread. Introducing needles are modified from serum needles by first removing the syringe fitting and then machining a longitudinal slot in the whole length of the needle. A small circular tab is fitted to the proximal end for handling purposes and to act as a guard against complete insertion into the tissues. The needles have a uniform slight curvature concave towards the longitudinal slot. Special holding forceps are used in order to avoid crushing the introducing needles. Balloon catheters are used.

Of the two methods described, one is used for interstitial implantation from within the bladder lumen and the other for interstitial implantation of the bladder from its exterior aspect in association with partial cystectomy. The use of each method is illustrated by a case history. The second method of performing a tantalum wire implant could well be used for fundal lesions without doing partial cystectomy. A small incision could be made in the bladder to allow one finger to be introduced into the lumen to palpate the lesion and act as a guide while implanting the affected area, the needles then being inserted in the bladder wall from its exterior aspect. Suprapubic drainage could be dispensed with and a balloon catheter of the Foley type left in the urethra. Special attention was given to the problem of uniformity of dosage, and observations made on dosage control are described.

Angiocardiographic Demonstration of Inoperability in Some Cases of Pulmonary Neoplasia. F. Soave and B. Possenti. Minerva chir. 11:793-798 (Sept. 15) 1956 (In Italian) [Turin, Italy].

The authors made a study of the value of angiocardiography as a means of establishing the operability of pulmonary neoplasms. Observations on 27 patients with pulmonary tumor from the periphery to the hilum are reported. A tumor in the hilar and parahilar regions can affect the vessels either by compression or by invasion. In case of compression the vessels show changes in the pattern, and in cases of invasion the morphology and the course of the affected vessel are markedly affected. Compression was found in 20 patients who were operated on on the basis of radiographic findings. The contrast medium showed invasion in the remaining seven patients. Thoracotomy confirmed the inoperability of the lesion.

BOOK REVIEWS

Atlas cerebri humani: The Inner Structure of the Brain Demonstrated on the Basis of Macroscopical Preparations. By E. Ludwig and J. Klingler. [In English, French, German and Italian.] Cloth. $18.50. Pp. 36, with 100 plates. Little, Brown & Company, 34 Beacon St., Boston 6; S. Karger AG., Arnold Böcklinstrasse 25, Basel, Switzerland, 1956.

The atlas contains a series of photographs of macroscopic specimens of the brain, prepared by the Klinger method of fixing in a formaldehyde solution, freezing, and dissecting while moist with special instruments. The freezing tends to spread the nerve fibers and, thus, makes them easier to handle. The photographs were taken with a Leica camera and enlarged to about 10 by 18 cm. Tracings, with the legend, mostly from Parisiensia Nomina Anatomica, adopted by the International Congress of Anatomy in Paris on July 30, 1955, accompany each plate. The text, which precedes the plates, gives details of the Klinger technique and the nomenclature used and is in German, French, English, and Italian. These excellently prepared specimens, known to anatomists for over 20 years, are reproduced so satisfactorily that the atlas will be indispensable for demonstrating the gross tracts of the brain in classes in anatomy. There is a good index and an up-to-date bibliography. The previous atlas (1938) by the same authors has long been out of print.

United States Army in World War II: The Technical Services. The Medical Department: Hospitalization and Evacuation, Zone of Interior. By Clarence McKittrick Smith. Cloth. $4. Pp. 503, with illustrations. Office of Chief of Military History, Department of the Army; Superintendent of Documents, Govern. Print. Off., Washington 25, D. C., 1956.

This is one of a series of volumes on the history of the medical department of the U. S. Army during World War II. It deals primarily with the logistics of hospitalization and evacuation in the zone of the interior. The professional care of patients is not discussed here but will be discussed by specialists in future volumes of this series. When the President proclaimed a limited national emergency Sept. 8, 1939, the Army medical department was operating only 7 general hospitals and 119 smaller station hospitals. The gigantic task before the medical department to meet the requirements of World War II is revealed in the fact that between January, 1942, and August, 1945, there were 8,900,000 admissions to Army hospitals in the zone of the interior. In the same period, more than 518,500 patients were debarked at seaports and 121,400 at airfields in the United States for transportation to hospitals. By the end of June, 1945, the number of patients on the rolls of Army hospitals in the United States rose to more than 318,000. How the medical department met this unprecedented task of hospitalization and evacuation is the subject of this volume.

Pharmacognosy: The Study of Natural Drug Substances and Certain Allied Products. By Robertson Pratt, Ph.D., Professor of Pharmacognosy and Antibiotics, University of California School of Pharmacy, San Francisco, and Heber W. Youngken Jr., Ph.D., Professor and Chairman for Pharmacognosy, University of Washington College of Pharmacy, Seattle. Second edition. Cloth. $10. Pp. 694, with 70 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada; Pitman Medical Publishing Co., Ltd., 39 Parker St., Kingsway, London, W.C.2, England, 1956.

This edition, as was the previous one published in 1951, is intended primarily for students of pharmacognosy and for practicing pharmacists. Various sections have been expanded due to the developments in such fields as the antibiotics and the tranquilizing drugs. The section on agents used for the control of insects has been enlarged to include toxicity and emergency treatment of poisoning caused by some of the newer insecticides of the organic phosphate group. An appendix, listing some of the common plants that exist in the United States, has been added to this edition, and it provides information on the treatment of accidental poisoning caused by them. In addition to providing a useful text for students of the pharmaceutical sciences, the book should be of value to physicians and to others interested in the study of natural drugs and allied materials.

Jews in the World of Science: A Biographical Dictionary of Jews Eminent in the Natural and Social Sciences. Edited by Harry Cohen and Itzhak J. Carmin. Contributing editors: J. Robert Oppenheimer, Meyer W. Weisgal, and Louis Gershenfeld. Cloth. $18. Pp. 263. Monde Publishers, Inc., P. O. Box 209, White Plains, New York, 1956.

In his preface Dr. Cohen quotes the famous statement of Pasteur to the effect that "la science n'a pas de patrie." He then proceeds to argue not only that science can have a fatherland but also that it can belong to a definite group—in this instance the Jews. There are tributes to Albert Einstein, Chaim Weizmann, Jonas E. Salk, and others. It apparently did not occur to the writer that, were it not for the great Ehrlich, also a Jew, there would be no Salk. The founder of the science of immunity, Ehrlich, is not mentioned anywhere in the volume and neither is Metchnikoff, who first described phagocytosis. On the other hand the names of physicians, whose only contribution to science was that they were born Jews, are included. The value of this opus to science, and for that matter to the Jews as a group, may be questioned in view of such limitations.

Pelvimetry. By Herbert Thoms, M.D. Cloth. $5. Pp. 120, with 45 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1956.

This small book presents a practical description of the variations and abnormalities of the bony pelvis in relation to labor and describes certain diagnostic procedures by which pelvic morphology and pelvic capacity can be ascertained. Thoms' has devoted a large part of his career to this subject. He was a pioneer in urging that all primigravidas have a combined clinical and roentgenologic survey of the bony pelvis. The book is the culmination of the author's numerous contributions to the literature in the past 25 years. It is well printed in clear type, and most of the illustrations have been clearly reproduced. A few of the line drawings lack the professional touch. Nevertheless, the book is a classic and should be diligently studied by all obstetricians and roentgenologists.

Thiopentone and Other Thiobarbiturates. By John W. Dundee, M.D., F.F.A.R.C.S., D.A. Cloth. $5. Pp. 312, with 59 illustrations. E. & S. Livingstone, Ltd., 16 and 17 Teviot Pl., Edinburgh 1, Scotland; Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1956.

This book should rapidly come to be considered one of the classics in the literature of anesthesia. The author has condensed into a relatively few pages the pertinent mass of literature that has accumulated on this vital subject. This book is logically and clearly prepared in a fashion that makes it easy and pleasant to read, yet it is definitely informative. Although the author does not hesitate to express his opinion, he gives due consideration to the controversial aspects of the subject and, in the final analysis, presents the reader with the known as well as the unknown of the subject of anesthesia. This book is organized into 12 chapters dealing with history; physical properties and chemistry; distribution and fate in the body; the effects of thiobarbiturates on the body; variations in response to thiobarbiturates; the use of thiopental sodium in certain pathological conditions; hazards, therapeutic uses, and administration of thiopental; some newer thiobarbiturates; and analeptics and other stimulants. There are excellent references given on each aspect of the subject. The conciseness and neatness of this book's organization should make it valuable as a reference book for all who are interested. It can, therefore, be recommended to libraries, anesthesiologists, surgeons, pharmacologists, and physiologists.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

STRENUOUS EXERCISE IN OLDER PERSONS

To the Editor:—*Please give the consensus among physicians of the advisability of strenuous exercises (such as weight lifting, running, or dancing—all of them up to a point short of exhaustion or even fatigue) in a healthy man in his early fifties.* *M.D., New York.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—If the man in his early fifties is healthy, strenuous exercise such as weight lifting, running, and dancing is not harmful. An individual's general health has great influence on his tolerance for such exercise. If he can tolerate it well, it is not believed there is any harm in following a program of activities of this kind. Care should be taken with regard to exercise for an individual whose health shows some defect.

Answer.—There is no known study providing evidence as to a consensus on the question. The following excerpts from a from a committee report in *Hygeia*, August, 1943, are pertinent.

> Among older persons (over 40) physical examinations and observation of the individual's reaction to exercise will disclose large numbers who need to restrict exercise.
>
> Individual variations in capacity for exercise are important. Some persons, even at early ages, react unfavorably to exercise through extreme exhaustion, breathlessness and emotional depression. It is not wise to expect these persons to reach the same level of physical achievement as do those to whom exercise is an exhilarant and a stimulant.
>
> Hard, fast, sustained or highly competitive games and sports should not be played by persons beyond the age of 35, unless they have been playing them continuously and have kept themselves fit and accustomed to these sports.
>
> The ability to recuperate after exercise is a good guide at any age. Recuperation should be reasonably prompt. If breathing and heart rate are still greatly accelerated at the end of ten minutes after exercise, and if there is marked weakness or fatigue persisting after a two hour rest period, restlessness after retiring for the night with broken sleep, or a sense of definite fatigue the day following, the exercise has been too severe or too prolonged for that person in his present stage of training and physical strength.
>
> Exercise should be graded according to age, capacity of the individual, and the state of his training and fitness. In general, exercise should be modified in the direction of less strenuous activities after the age of 40.
>
> Since performance in any activity is fundamentally conditioned by the age, sex, and physical capacity of the participants, it follows that the amount of effort actually exerted by each individual will more significantly determine the contribution of the activity to his physical fitness than will the rules or other specifications that give form to the activity.

TRICHOMONAS INFECTION

To the Editor:—*Please suggest treatment of chronic urinary infection with trichomonads as the chief offending organisms. I have tried all the available antibiotic agents. Tritheon was also used.* *M.D., Florida.*

Answer.—It is taken for granted that the patient in question is a female. Infection in the urinary tract with trichomonads is usually of vaginal origin, and an attempt should first be made to eliminate vaginal infection. As is well known, this may be difficult to accomplish. Numerous trichomonacidal agents are available, but few, if any, seem to eliminate this organism permanently. The patient may have symptomatic relief and the trichomonads may disappear temporarily, but if subsequent vaginal cultures are made they are usually found to be present. It is particularly difficult to eliminate them, when present in the Skene's or Bartholin's glands. In the treatment of trichomonas infection, attention must be given to the male partner, and on examination of the semen in such cases trichomonads will be found in a high percentage of cases. Simultaneous treatment of both wife and husband should be given if the latter is found to be the carrier. Although Tritheon (2-acetylamino-5-nitrothiazole) has not been of value in this case, many observers have found it to be quite efficacious when administered to both the male and the female involved.

In this case, the chief problem seems to be a chronic urinary infection. While trichomonads often are found in the urine of patients suffering with vaginal trichomonas infections, they may be incidental invaders and cause little or no urinary symptoms. If there is definite evidence of chronic urinary infection present, the etiological organism is probably other than trichomonal. It would be necessary to have cultures made of the urine to determine the types of bacterial infection present. Such infection may be caused by a variety of lesions involving the urinary tract, which will have to be identified. As with every chronic urinary infection, a thorough and careful examination of the urinary tract, including cystoscopic examination with catheterization of the ureters and urographic examinations, is indicated.

CAUDAL ANESTHESIA IN OBSTETRICS

To the Editor:—*Does Hingson still use caudal anesthesia in obstetrics, or does he now prefer the saddle block method? Is there any center in the eastern United States where the Hingson caudal method is taught? At a local hospital the trocar and catheter method is used with a high percentage of failures. Is this method recommended in preference to methods with flexible needle?* *M.D., Massachusetts.*

Answer.—During 1955, continuous caudal analgesia was administered in the department of anesthesia at the University Hospitals of Cleveland 625 times, of which 595 uses were for obstetric labor and delivery. Saddle block spinal anesthesia was administered 2,558 times in obstetrics on the same service. "Anesthesia for Obstetrics," by Hingson and Hellman (Philadelphia, J. B. Lippincott Company, 1956, p. 182) contains statistical data from 8,000 consecutive labors and deliveries supervised by Hingson and his staff, in which 28% of the private patients and 16% of staff patients in Johns Hopkins Hospital had caudal analgesia, with spinal being used in 13%; whereas the adjoining Sinai Hospital utilized caudal analgesia in 18% and spinal in 60%. Caudal analgesia is to be preferred for patients with systemic diseases and for primiparas undergoing long hours of labor, provided that the caudal is instituted after 5 cm. of cervical dilatation for precipitous or rapid labors, with systemic sedation preliminary to a low-dose spinal anesthesia for delivery. Continuous caudal analgesia is being used for the majority of cases in the Beth El Hospital in Brooklyn, N. Y., and for a large percentage in the Mount Sinai Hospital in Manhattan. More than 60 centers in the United States use this method regularly; for example, the maternity service at Fort Sam Houston, Texas, has conducted more than 16,000 deliveries with this technique. Many anesthesia residencies are teaching this method, for example, Columbia University Hospitals, Manhattan; Western Reserve University, Cleveland; Mason Clinic, Seattle; and Stanford University, San Francisco. At the present time, there are no intensive courses on this subject being given for short periods.

CHLORINATION OF WATER

To the Editor:—*What measures should be taken in a small community in which the municipal water samples are returned from the state laboratory frequently as being unsafe "due to high coliform count"? These samples are unsafe in spite of apparently adequate chlorination. There have been sporadic cases of typhoid in this area.* *M.D., Colorado.*

Answer:—A chlorinated municipal water supply that continually has specimens showing high coliform indexes is either one using water of a quality for which simple chlorination is not a satisfactory method of treatment or one for which the methods of application and control used are inadequate. On the

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

basis of the limited information given, these two points are to be considered: 1. Certain sources of water have a high color and turbidity and contain a large amount of organic and inorganic matter and a high bacteria content. Simple chlorination cannot be successfully used in such cases. Here other types of treatment are indicated, such as coagulation and filtration, supplemented with chlorination. 2. If the source water is of satisfactory quality for simple chlorination, then, to be effective, chlorine must be added under controlled conditions, that is, by trained personnel, with adequate equipment and properly selected points of application. A knowledge of the chlorine demand of the water is necessary so that, when chlorine is added, the proper amount is used to satisfy this demand and still to leave a residual of approximately 0.5 ppm in the most remote part of the distribution system.

The above conditions may change periodically, hence, it is imperative to control the addition of chlorine and make regular residual chlorine tests, at least daily. It is suggested that, in organizing the control methods, the assistance of a qualified sanitary engineer be obtained. Regarding the advisability of mass typhoid inoculations, the local and state health authorities should be consulted.

EXPOSURE TO TRICHLOROETHYLENE

To the Editor:—*Is prolonged exposure to trichloroethylene vapor likely to cause renal damage?*

M.D., South Carolina.

Answer.—The current belief is that trichloroethylene seldom leads to renal involvement. This statement applies alike to acute and chronic poisoning. In fact, there is wide denial that a chronic state arises and affirmation that trichloroethylene does not lend itself to cumulative effects. Johnstone categorically states: "The kidneys or liver are not commonly injured by trichloroethylene." The following statement is taken from Browning: "Most authorities appear to consider that nephritis as a sequel is unknown. Stüber (1931) states that the kidneys are never affected. Roholm (1933), however, mentions acute nephritis as a manifestation of severe poisoning." Von Oettingen makes these observations in connection with animal experiments: "With regard to pathological changes in the kidneys, Wright and Schaffer (1932) noted in dogs after oral doses of 5 cc. per kg. cloudy swelling and congestion of these organs. Bose and Mukerji (1944) reported no liver injury but signs of acute toxic nephritis. Lehmann and Schmidt-Kehl (1936) saw, after repeated exposure of rabbits, cloudy swelling and hyperemia with fatty infiltration. Similar findings were reported by Herzberg (1934), and Dervillée, Nun, and Casts (1939) saw regularly, lesions in the convoluted tubules of rabbits after oral doses, whereas the glomerular apparatus was not affected." From industrial exposure renal damage is practically unknown, and the same statement applies to the use of trichloroethylene for anesthetic purposes. The foremost locus of action of trichloroethylene is the central nervous system.

STINGING TENTACLES OF JELLYFISH

To the Editor:—*What is the "stinging" chemical that one contacts with the tentacles of the "sting nettle" of the Chesapeake Bay? This marine animal is of the jellyfish family and abounds in the water near the rivers of the tidewater region. What is the best medicament to apply to the skin after contact, to relieve the stinging pain? What precautions and what medicament should be used when a swimmer's eyes have been "stung"? Is there any method for ridding the water of these creatures?*

Harold W. Felton, M.D., Deltaville, Va.

Answer.—Studies on extracts of coelenterate tentacles indicate that the pain-producing factor is probably 5-hydroxytryptamine. The concomitant paralysis may be due to two or more related quaternary ammonium bases such as tetramethylammonium and urocanylcholine. Treatment of coelenterate stings should be directed toward accomplishing their primary objectives: relieving pain, alleviating neurotoxic effects, and controlling primary shock. Morphine sulfate is effective in relieving pain. Calcium gluconate 4 gives prompt relief of muscular spasms; oral antihistaminics and topical creams afford alleviation of urticarial lesions and symptoms as do ammonium hydroxide, sodium bicarbonate, olive oil, and ethyl alcohol. Artificial respiration, cardiac and respiratory stimulants, and other supportive measures may be required. If a swimmer's eyes should be stung, any one of the remedies mentioned above that would not be harmful by itself may be used. There is no practical method of ridding the water of noxious coelenterates. Avoidance of the animals, whether in the water or on the beach, is the best prophylaxis.

SURGERY OF FALLOPIAN TUBES

To the Editor:—*What is the approximate percentage of pregnancies obtained after surgery on fallopian tubes? Does the procedure for repair of a tubal closure depend to a certain extent on where the tubes are closed? What procedure can be considered favorably? What is the percentage of ruptured fallopian tubes and the percentage of serious hemorrhages?*

Howard Starret, M.D., Cuernavaca, Morelos, Mexico.

Answer.—A year ago Siegler and Hellman summarized the results of salpingoplastic operations in the practices of 734 qualified specialists. Pregnancy occurred in 22.6% of the cases reported. Of the pregnancies obtained, about 15% terminated in abortion, 9% in ectopic gestation, and 74% in live births. The high incidence of extrauterine pregnancy, is, unfortunately, a feature to be expected in a group of cases in which the tubes are more or less damaged. Rupture and serious hemorrhage should rarely happen in women who are under the close observation of competent gynecologists. The chances of success are greatest when the obstruction is located at the fimbriated ends of tubes not otherwise notably affected by inflammatory disease. Of 77 operations performed by this consultant in similar cases, 28 resulted in the birth of living children. Each of the newer techniques for maintaining patency postoperatively has at least theoretical advantages, together with some disadvantages. After salpingostomy for fimbriated-end occlusion, this consultant relies mainly on early and repeated injection of iodized oil and insufflation of gas.

PERFORATION OF CORNEA

To the Editor:—*Occasionally, I have had to remove deeply embedded foreign bodies from the cornea under local anesthesia produced with Dorsacaine. At times, I have had to scrape gently but deeply with an eye spud to get all the particles out. Suppose I perforated the cornea on one of these attempts. How should I treat such an injury if it did occur? I am not an eye specialist, and I am 40 miles from the nearest medical center.*

M.D., Oregon.

Answer.—The cornea is surprisingly resistant to perforation with an eye spud. A more common complication than perforation is pushing the foreign body through the cornea into the anterior chamber. If this occurs the pupil should be constricted, provided the foreign body is anterior to the iris. Then the patient should be transported to special care, with the head in such a position that the foreign body cannot go through the pupil into the interior of the eye. If the anterior chamber is entered with an eye spud, there is a sudden loss of aqueous, which causes the iris to touch the cornea. Usually the opening is so minute that it is closed by fibrin in the reformed aqueous and the eye quickly heals. Immediately following such a perforation, it is advisable that both eyes be patched and that the patient be placed supine on a litter and transported by ambulance to the closest eye specialist.

DRUGS INTERFERING WITH PROTEIN-BOUND IODINE DETERMINATION

To the Editor:—*I would like a list of drugs that contain the iodide radical capable of giving a disturbed protein-bound iodine level.*

John D. Lynch, M.D., Manitowoc, Wis.

Answer.—Organic iodine-containing compounds known to effect protein-bound iodine determinations include iodine-containing radiopaque dyes used in angiocardiography, cholecystography, urography, bronchography, or myelography; iodinated amebicides (chiniofon, iodochlorhydroxyquin, and diiodohydroxyquin); vaginal suppositories such as Floraquin, which contains diiodohydroxyquin; penicillin G diethylaminoethyl ester hydriodide (Neo-Penil); and iothiouracil. Preparations containing inorganic iodine include Lugol's solution, tincture of iodine, and syrup of hydriodic acid. Certain vitamin and cod liver oil preparations may also be rich in iodine, while barium sulfate is said to give rise to elevated protein-bound iodine due to contaminating iodine. Sulfobromophthalein (Bromsulphalein) dye, though not containing iodine, also causes elevation of plasma protein-bound iodine. Due to the widespread use of iodide-containing compounds and the frequent difficulty of obtaining a history of exposure to such drugs, some laboratories now determine inorganic iodine in addition to protein-bound iodine, as an aid to the detection of spuriously high values.

PREDNISONE FOR ASTHMA

To the Editor:—*A 10-year-old boy has had bronchial asthma every fall since he was one year of age. The usual drugs for wheezing—ephedrine, aminophylline, adrenalin, and sedatives—have little effect in terminating his attacks, but doses of 2.5 mg. of prednisone given eight hours apart for nine doses clear up the attacks. He is being desensitized against inhalants and foods. Is it better to use prednisone each time an attack occurs or to treat with the usual bronchodilators? Would it be of any advantage to keep him on therapy with 5 mg. of prednisone daily during the fall season?*

A. McCray Jones, M.D., Whaleyville, Va.

Answer.—Considering the ineffectiveness of the usual medication and the response to small doses of prednisone in this case, it would certainly be better to use the latter when an asthma attack occurs. Whether one should give the prednisone during the entire fall season would depend somewhat on the history of the boy's reaction to the drug. If he is symptom-free for some time after the hormone is used, it would be preferable to use it only when a new attack occurs. If, however, symptoms tend to persist and moderate doses keep the boy well, it is perfectly proper to use it during the entire season.

ABSENCE OF THE APPENDIX

To the Editor:—*An 8-year-old boy with a diagnosis of chronic appendicitis was operated on. A McBurney incision was made and no appendix appeared, though the incision was enlarged twice. The cecum was normally placed, and at the junction of the ilium and the cecum there was only a rich vascularization without any trace of appendix. The chief surgeon's help was immediately requested and after a half-hour's search, following my own search for an hour, the abdomen was closed with no appendix having been found. How can this be explained?*

Juan Rodriguez, M.D., Matanzas, Cuba.

Answer.—Granting that the retrocecally placed appendix can lie subserosally along the cecum and can be difficult to find, it seems doubtful from the description given that such was the case. Congenital absence of the appendix is apparently quite rare, but occasional cases have been reported. Spivack (Am. J. Surg. 13:297, 1931) has felt that some cases of this type represent hypoplasia rather than actual agenesis of the appendix. Perhaps this patient presented the very rare instance of congenital absence of the appendix.

ZINC DEFICIENCY AND LEUKEMIA

To the Editor:—*Is there any scientific evidence to support a statement in the lay press that there appears to be a definite relation between leukemia and a deficiency, probably dietary, in the so-called trace elements, especially zinc?*

W. B. Cox, M.D., Missoula, Mont.

Answer.—There is no evidence that a deficiency of a trace element such as zinc causes leukemia. The statements in the lay press referred to in the query may have been derived from findings that some leukemic cells contain less zinc than normal leukocytes. Leukemic cells (as neoplastic cells in general) are poor in some normal components; e. g., myeloid leukemic cells contain less alkaline phosphatases than normal cells but this is no proof of causal relationships. Concerning zinc in leukocytes, see Bert L. Vallee, Trace Elements and Pathologic States, in "Principles of Internal Medicine" (Harrison, T. R., and others, editors, New York, Blakiston Company, 1954).

RESEARCH REVIEWS

From time to time there will be published in this section of The Journal *brief but not necessarily complete reviews of some of the newer clinical aspects of medical research and practice. This material is gathered specifically for* The Journal.—Ed.

VIRUSES

New laboratory techniques have led to the identification of many previously unrecognized viruses. In fact, the problem today is no longer isolation and recognition of new viruses but to know whether they cause disease.

A meeting that was held recently is characteristic of the present situation. Its title was "Conference on Viruses in Seach of Disease."[1] Among the viruses recently discovered are a group found in the respiratory tract and conjunctivas of man, which has been referred to by various names: adenoid degenerative (AD), later called adenoidal-pharyngeal-conjunctival (APC) viruses; respiratory illness (RI) agents; acute respiratory disease (ARD) group. To avoid confusion, some of the investigators active in this field met in New York in May and decided to replace all these names by the term adenovirus.

So far, more than 500 strains of adenoviruses have been isolated. They have been grouped together into serologic types; 13 of these types have been identified in material from human sources.[2]

The question whether they cause clinically manifest disease has been answered for some of these serotypes: Hilleman[3] pointed to the etiological relation between RI-67 and respiratory disease in 1954. He showed that RI-67 (now known as adenovirus type 4) was associated with acute respiratory disease (ARD) and primary atypical pneumonia (PAP) among soldiers. It is now known that types 3, 4, and 7 cause acute febrile respiratory illnesses in young adults.[4]

At the National Institutes of Health in Bethesda, Md., adenovirus type 3 was recognized as the cause of pharyngoconjunctival fever,[5] a syndrome characterized by pharyngitis, conjunctivitis, fever, malaise, and cervical adenopathy. Type 3 has been found in persons of all age groups.

Less certain is the causal relation between acute febrile upper respiratory tract illness and adenovirus types 1, 2, and 5. These serotypes occur mostly in infants and young children. The multiplicity of infecting agents and the frequency of febrile illnesses in this age group complicate the problem.[2]

It is thought that the conjunctivas may be the portal of entry in some cases. Adenovirus types 6 and 8 appear to be specifically related to ocular disease, type 6 to follicular conjunctivitis and type 8 to keratoconjunctivitis.

Recognition of an etiological relation between adenoviruses and clinical disease has led to attempts at protecting those most exposed to these infections by vaccination. A type 3 vaccine prepared in the laboratory was tested in young adult volunteers.[6] It gave satisfactory protection.

At the Walter Reed Army Institute of Research, Washington, D. C., a bivalent (types 4 and 7) vaccine was prepared and found to be highly effective in reducing the incidence of acute respiratory illness of adenovirus etiology in recruits.[7]

A joint study with use of a commercially prepared trivalent (types 3, 4, and 7) vaccine has been in progress since December, 1955. The Naval Medical Research Unit Nr.4, the National Institutes of Health, and the University of Chicago have been cooperating. The vaccine has been given by a single intramuscular injection to about 4,000 naval recruits; another 12,000 recruits served as controls. Of these, about one-third have completed their training. Analysis of the results obtained in this group shows that the vaccine gave protection in a significantly high proportion. There were no local or general reactions following inoculation.[8]

There has been progress also *in elucidating the etiological role of other viruses.* At the meeting mentioned above, A. J. Rhodes,[9] the Hospital for Sick Children, Toronto, reported that Coxsackie viruses of Dalldorf's group B have been found to be a cause of aseptic meningitis in children. It has been known for some time now that these viruses are also associated with pleurodynia. H. M. Meyer Jr. and his co-workers,[10] the Central Virus Diagnostic Laboratory for the Armed Services, Walter Reed Army Institute of Research, Washington, D. C., recovered Coxsackie viruses group B and orphan viruses from specimens from the alimentary tract of patients with clinical cases of aseptic meningitis. Three of the four Coxsackie viruses found belonged to serotype B-3 and the other to serotype B-2. The 13 orphan viruses recovered fell into three serologic groups: Walter Reed 1, 2, and 3. Eleven of the orphan viruses found were in the WR-1 group, the rest in groups WR-2 and WR-3. *A comparison* between WR orphan strains and ECHO viruses was made: It was found that WR-1 was related to ECHO-6, and WR-3 to ECHO-2. After having carefully excluded other agents known to cause aseptic meningitis, these workers believe that these viruses are etiologically related to the disease. They were recovered during the acute phase of the illness and there was a significant increase in specific antibody during convalescence. Specimens in this investigation came from widely separated areas: Massachusetts, the area around Washington, D. C., Florida, and California. It is of importance that these viruses may be definitely considered to be a cause of aseptic meningitis clinically indistinguishable from nonparalytic poliomyelitis

R. H. Parrott,[11] National Institutes of Health, Bethesda, Md., recovered Coxsackie virus group A from 84% of cases of herpangina (vesicular pharyngitis). In his opinion these viruses are associated with the disease. The serotypes isolated have been consistently the same six: A-2, A-4, A-5, A-6, A-8, and A-10. Most cases of herpangina can be distinguished clinically from gingivostomatitis.[12]

In the field of *chemotherapy* of virus diseases one of the difficulties has been that selective poisoning of the parasite without harming the host presents problems different from those encountered in some bacterial diseases. This was pointed out by F. M. Schabel Jr.,[13] Southern Research Institute, Birmingham, Ala., who recently reviewed the subject. He thought that exploitable biochemical differences between host cells and viruses may lie in protein and nucleic acid metabolism. While viruses reproduce at the expense of the host cells, using their energy sources and building blocks, they put the building blocks together in a different way, forming different proteins and nucleic acids. Experimental work with compounds derived from antibiotics promises to lead to a better understanding of these mechanisms. Noformicin (Mk-61) obtained from Nocardia is active in mice and eggs against human influenza virus (types A, A′, B) and against swine influenza; in eggs it is active against mumps and Newcastle disease virus. Ehrlichin and Netropsin derived from Streptomyces are active against influenza (type B) and vaccinia (WR strain). The toxicity of some of these compounds in man is an obstacle to their therapeutic use.

At another meeting, P. K. Smith and his associates,[14] the George Washington University, Washington, D. C., presented papers on the action of canavanine flavianate, which inhibits the growth of influenza A virus (WS strain) in tissue cultures of dispersed chick embryo lungs, and on compounds in the thiosemicarbazone and diphenyl group. Ten of these and related substances showed significant action against influenza virus, strain A, PR8. Seven drugs were tested by oral feeding to mice, beginning one day prior to infection; some of these gave appreciable protection. All control animals in this experiment died within eight days.

Strenuous efforts are being made at present in a rational approach to virus chemotherapy. Thousands of compounds have already been tested in many research centers. So far, none are known to hold definite promise of clinical success.

HEALTH LEGISLATION

As newly elected members of the 85th Congress and holdover members from the 84th assemble in January for another two years, health legislation will be high on the domestic agenda. On the health list, in turn, three proposals now stand out above all others. They are federal grants for medical school construction, federal employees health insurance, and pooling arrangements to stimulate insurance companies to broaden voluntary health plans.

Whether these and other health proposals are enacted this session will depend in some degree on the administration's desire to push them in the face of new demands on the federal treasury. The world situation has placed emphasis on dollars for defense.

Cognizant of this, Secretary Folsom says that, while "we must maintain this defense posture, we want to be very careful that we don't let down on expenditures in the field of health, education, and welfare." The Secretary of the Department of Health, Education, and Welfare adds: "We have also to look out for our human resources: To see that the people are well educated, that we cut down illness as much as we can, and that we also provide a sense of economic security for the older people."

Groundwork already has been laid for consideration of medical school aid. The staff of the House Interstate and Foreign Commerce Committee has prepared a report on background information relating to schools of medicine, dentistry, osteopathy, and public health. The report is an outgrowth of a questionnaire sent to more than 50 organizations and groups, in which they were asked to supply information on a wide range of subjects within the framework of medical education and physician supply.

The administration sought last session to get medical school construction aid made a part of the laboratory research facilities bill, but Congress decided to defer action. Now the way appears clear for a full-dress study of the question in the coming session.

Another proposal in which a vast amount of time and staff work has been expended is federal workers' health insurance. The Civil Service Commission is seeking a new approach that would combine earlier plans for both basic coverage and major medical expenses. The commission hopes to reconcile the conflicting views of nonprofit plans (Blue Cross and Blue Shield), of commercial carriers, and of federal employees unions.

The last effort, a proposal for major medical coverage with the government paying the premiums, failed to get through the 84th Congress after objections by nonprofit and union spokesmen. An even earlier plan for basic coverage with a sharing of premiums between government and worker foundered over the issues of administrative costs and the extent of government payment of premiums.

The third health item certain to be pursued, with strong administration backing, is Secretary Folsom's plan for allowing the pooling facilities of smaller insurance companies, which would be facilitated through the waiving of antitrust laws. The theory is that this would encourage companies to experiment in new fields, such as catastrophic insurance and plans for the aged.

This proposal is a substitute for the long-dormant reinsurance plan, under which the federal government would move into the health field through a federal reinsurance fund. In other words, it would guarantee losses up to a certain percentage for those companies that took out reinsurance and suffered losses because of experimentation. Mr. Folsom has indicated the administration still favors this in principle but admits chances of passage are slim. Congress rejected the idea two years ago.

There has been considerable activity already in the proposal for tax deferment of money paid by the self-employed into retirement plans—the Jenkins-Keogh type bills. The idea appears to have majority support among House members, but there could be one hitch: a reluctance of legislators in the final showdown to give preferred tax treatment when no general tax cut is in the offing.

Congress will have to take action in the military medical field before July 1, when the "doctor-draft" expires. In all likelihood the regular draft will be amended to provide the means for the orderly call-up of doctors and other scientific personnel under age 35 who have not served their time under the regular draft. The Armed Services are making efforts to encourage medical school graduates to take intern and residency training under a special deferment program in which doctors promise later active service.

Congress could enact no new legislation this session and it would still have to vote large sums of money for existing health programs. They include Hill-Burton hospital construction, laboratory facilities, public health and nurse training grants, water and air pollution control, and, looming larger than ever, money for more medical research. In the field of research, Congress has shown no inclination to slow down its giving.

RESEARCH FACILITIES GRANTS

Seventy-three grants totaling $24,460,467 have been awarded by the Public Health Service to help institutions build additional health research facilities under a program enacted at the last session of Congress. The law authorizes grants totaling 90 million dollars to be spent over three years at the rate of 30 million dollars annually. Money must be matched 50-50 by the recipient. Grants are approved by the surgeon general of

Washington News—Continued

the Public Health Service, on recommendations of the National Advisory Council on Health Research Facilities.

In September, seven grants totaling $765,159 were approved. In approving the new group, the council deferred action on about 50 others. The next meeting of the council is scheduled for March. In announcing the awards, Surgeon General Burney explained that for the present the emphasis will be on construction grants, although the new law also authorizes grants to help in purchasing equipment. He said: "The approved grants were recommended by the council for the construction of research facilities and do not include funds for movable equipment. The council felt that, in order to get more facilities underway more rapidly with currently available funds, and in face of the large need as shown by the $66,888,239 in completed applications, and $49,160,774 in letters of intent from institutions desiring to apply for aid, it should provide awards this first year of the program for buildings. The council also felt that in the program's ensuing years assistance toward essential equipment for the research buildings can be provided."

The two largest of the new grants (each a million and a half dollars) went to Stanford University Medical School and the University of Utah College of Medicine for new research facilities buildings. Other large grants include: University of Alabama Medical Center, $1,033,500; California Institute of Technology, $477,000; University of Southern California, $854,000, Yale University, School of Medicine, $461,612; University of Miami, $941,720; University of Chicago, Division of Biological Sciences, $250,000; University of Kentucky, $1,208,992; Johns Hopkins University, $960,000; Retina Foundation, $300,000; New England Center Hospital, $400,000; Wayne State University, College of Medicine, $900,000; University of Michigan, School of Public Health, $605,000; University of Michigan, $600,000; Sloan-Kettering Institute for Cancer Research, $900,000; Roswell Park Memorial Institute, $646,000; Rockefeller Institute for Medical Research, $600,000; University of Buffalo, $463,020 (School of Medicine); University of Cincinnati College of Medicine, $865,688; Ohio State University College of Medicine, $900,000; University of Pittsburgh, $649,312, University of Pennsylvania, Medical Division, $400,000; Brown University, $411,002; and University of Wisconsin, Medical School, $975,000.

VETERANS HOSPITALS

The Veterans Administration reports that more efficient use of bed space has given it the equivalent of another 1,700-bed mental hospital in the past four years. In releasing the details, Dr. J. F. Casey, head of the VA's psychiatric and neurological service in Washington, D. C., said approximately that number of beds have been freed in mental hospitals since 1952 through transfer of elderly, chronic mental patients with physical illnesses to general and surgical hospitals that offer special care to aged patients.

All of the patients were moved to the hospitals nearest their homes staffed to give psychiatric as well as general medical treatment. The patient's consent was obtained in every case. Dr. Casey said the beds vacated in mental hospitals were filled immediately by veterans with acute mental illnesses who had been waiting admission. Patients transferred were described as "those whose mental illnesses had become stabilized and resistant to treatment for 10 to 20 years, so that their chronic physical illnesses were predominant."

NATIONAL LIBRARY OF MEDICINE

During the fiscal year that ended last June 30, the National Library of Medicine acquired 9,420 books, 69,367 serial pieces, and 1,130 new serial titles. The library was known as the Armed Forces Medical Library until this year, when Congress changed its name and placed it under the Department of Health, Education, and Welfare. In its annual report, the library cited these additional statistics: Spent $1,215,274 for all operations and employed a force of 209 persons, purchased 309 old and rare items for the history of medicine division, cataloged 19,841 titles; bound 12,824 volumes; added 2,417 pictures and portraits to its art collection, prepared 19,332 main entries for the 1955 volume of the library catalog; circulated 117,026 volumes, answered 6,722 reference questions; and filmed 1,499,075 pages in response to 83,972 photoduplication orders.

MISCELLANY

Brig. Gen. Harold Willard Glattly will retire early next year from the Army Medical Corps. He received the Legion of Merit for his "selfless performance to fellow prisoners" while in Japanese custody. . . . Salvatore G. DiMichael has been named New York City Regional Representative of the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare . . . "New Perspectives for Research on Juvenile Delinquency," recently published by the Children's Bureau of HEW, is the report of a conference on the interrelation and relevance of sociological and psychiatric concepts to delinquency. It may be obtained from the Government Printing Office, Washington, D. C., for 30 cents a copy. . . . A federal court in Virginia has allowed an income tax deduction for the cost of installing a detachable invalid elevator, without medical advice, for a person suffering from osteoarthritis. The court stated that this was not an expenditure for capital improvement "but to lessen the aggravation of an existing condition." It did not discuss whether medical advice was a prerequisite for a medical expense deduction. . . . With President Eisenhower and Secretary Folsom urging the general public to have the three poliomyelitis shots, two large producers of Salk vaccine (Eli Lilly & Company and Pitman-Moore Company) announce substantial cutbacks in serum production. At present it is estimated 20 million poliomyelitis shots are in storage in the United States. . . . An employment profile of scientists in 1954 and 1955 has been released by the National Science Foundation. The report, based on data collected from 94,000 scientists, finds that 41% had Ph.D. degrees, 25% M.A. degrees, and 32% A.B. or first professional degrees. . . . The National Naval Medical Center at Bethesda, Md., received a plaque from the officers and men of the Pakistan Naval Hospital, Karachi, Pakistan, for assistance in providing training in various medical specialties for Pakistani officers. . . . The state of Texas and the United States Air Force recently held a joint conference on traffic safety to discuss ways of reducing traffic accidents among air force personnel on public highways.

(cont'd)

'LANOXIN' continues to offer the same advantages — only the name has been changed.

The full effects of each dose develop quickly to permit rapid appraisal of the need for additional drug. Moreover, the limits of the patient's therapeutic range, which may be reduced in the seriously ill, may be approached with relative safety because toxicity, if it develops, soon abates. For true balance and uniformity of therapeutic effect, prescribe 'LANOXIN' brand Digoxin.

Sincerely,

'B.W.&Co.'

TABLETS: 0.25 mg. (white) and 0.5 mg. (green)

ELIXIR PEDIATRIC: 0.05 mg. in each cc.

AMPULS: 0.5 mg. in 2 cc.

INDICATIONS FOR VACCINATION AGAINST POLIOMYELITIS

John R. Paul, M.D., New Haven, Conn.

• *Immunity to poliomyelitis comes about naturally and early in life in some unvaccinated populations. In others, high susceptibility prevails in all age groups so that severe epidemics involve children, parents, and grandparents. In the United States differences exist not only between states but even within cities, and in general the people in the poorest urban areas become immune early in life. It is a question whether vaccination with the killed antigen will prepare young people, for instance, to resist the risk young parents face when exposed to the infection by their own children. If it turns out that natural infection helps to keep up the individual's immunity, it may be necessary to have the feeding of live virus regularly follow the inoculation of killed vaccine. The invaluable start that has been made should not be regarded as the final technique of immunization against poliomyelitis.*

With the ever-increasing use in the United States of a formalinized (killed virus) antipoliomyelitis vaccine (the Salk vaccine), which now has been administered to many millions of children, one can entertain the reasonable hope that by the end of 1956 there will have been a substantial reduction in the annual quota of cases of paralytic poliomyelitis in this country. During the last 14 months, safety factors in the preparation of this vaccine seem to have been successfully controlled; it has been demonstrated that some degree of immunity to the most severe (paralytic) forms of this infection has been established in a large percentage of the vaccinees and this immunity may last at least one to two years. Among the important problems to be discussed are (1) how this vaccination will affect the rate at which and degree to which vaccinees acquire subsequent inapparent alimentary infections with polioviruses (the only evidences of these infections are the excretion of virus from the throat or intestinal tract and the coincidental development of antibodies) and (2) what the ultimate duration of immunity to paralytic poliomyelitis will be. Careful laboratory observations will soon answer the first question. Time will eventually answer the second.

Naturally Acquired Immunity

My approach to this problem will be to consider how immunity to poliomyelitis comes about naturally in populations unvaccinated against poliomyelitis and what leads can be obtained from such experience to indicate who should be vaccinated and how often. It is common knowledge that most of us have been infected subclinically, i. e., so-called alimentary infections with one or more types of poliovirus during childhood and thereby have gained our immunity. However, it is not common knowledge that reinfection of this kind, with the same type of poliovirus, can be readily induced artificially. Koprowski[1] and Sabin[2] have shown that individuals sometimes may be infected artificially more than once with the same type of attenuated poliovirus and, indeed, the same strain.

Practical questions about this are as follows: 1. How soon would one expect immunity to decline in persons vaccinated with the formalinized (Salk) vaccine according to the present schedules? Regardless of whether immunity declines rapidly or slowly, will a full course of revaccination, or a series of so-called booster inoculations be indicated in children, adolescents, and young adults every few years or so? 2. On the other hand, to what extent can one depend upon natural alimentary infections or reinfections in a vaccinated child to keep his or her immunity automatically in constant repair? By this I mean the maintenance of immunity against both severe and mild infections, not only for 5 or 10 years but for life. That paralytic infections may occur in a certain percentage of immunized vaccinees is recognized. Less is known about the prevalence of alimentary infections in vaccinees, but that such mild infections may occur (within 12 months of vaccination) is an established fact from field observations made by several groups in 1954 and 1955, although in 1955 the full course of vaccination was not given. That an alimentary infection may be experimentally induced in a vaccinee has been demonstrated at least once, when feeding

of type 3 attenuated poliovirus was carried out in a child 9 years of age vaccinated one month previously with two doses of Salk vaccine. In this child, a postvaccinal alimentary infection was quickly established,[3] and virus was excreted for at least 39 days subsequently.

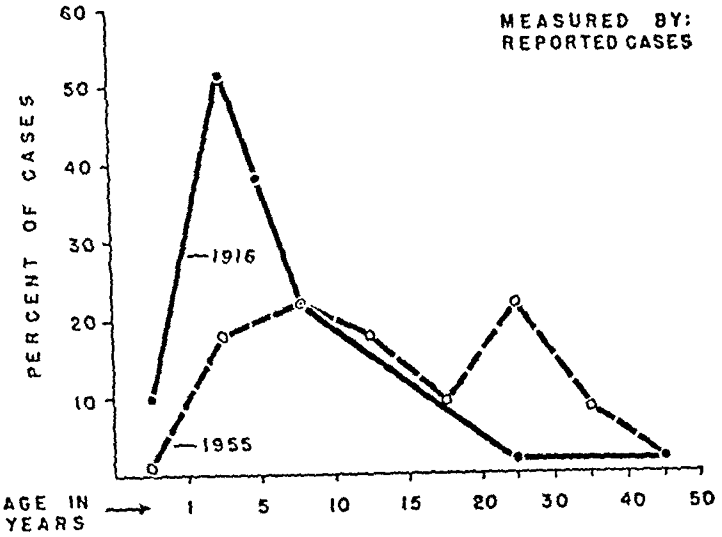

Fig. 1.—Comparison of age distribution of poliomyelitis cases in Connecticut in 1916 and 1955. (Data from Dr. James C. Hart and Dr. Mila E. Rindge, Bureau of Preventable Diseases, Connecticut State Department of Health, Hartford, Conn.)

Methods of Measuring Immunity

Before considering the role natural infections may play in the maintenance of the immunity of a vaccinated child, it seems worthwhile to review the status of immunity or susceptibility in various unvaccinated populations, both in this country and abroad. There are at present at least two ways of measuring immunity or susceptibility to this disease in a sample of a given population. One of these is by a serologic survey, the other by recording the ages at which clinical poliomyelitis infections occur. The former calls for testing of blood specimens for antibodies (against the three types of poliovirus). Such a sample should cover all age groups under 30 years and, I might add, may advantageously also cover groups representing different kinds of geographical or socioeconomic environments.

I do not have to emphasize here that presence of antibodies and immunity are not synonymous. Only indirectly does the presence of specific antibodies of a given titer in a previously infected or immunized individual suggest that the individual may resist subsequent poliomyelitis infection, provided he is not too heavily exposed to virus.

The second method of estimating immunity against poliomyelitis within a population is to record the ages at which clinical poliomyelitis is or has been actually acquired within a given period of time. If, for instance, all of the poliomyelitis cases recognized clinically within a given population are limited to children, this usually means that the local adult population is probably immune. An illustration of this approach can be found in figure 1, where the percentage of clinical cases of poliomyelitis in various age groups, as recorded in the state of Connecticut, in two different epidemic years (1916 and 1955) is charted. One can estimate how different the immune status was between these two populations, separated by a period of 40 years, by considering the differences in the age groups in these two series of patients. Correspondingly, the indications for vaccination might have differed in them. In one, that of 1916, the population was apparently solidly immune to paralytic poliomyelitis by the age of 20, while in the other, in 1955, immunity in the young adult population was far from solid, for there were many cases in the age period of 20 to 30.

One could go far afield here and point to geographical areas with inhabitants who have practically no immunity to poliomyelitis, such as those in arctic regions, where, so far, polioviruses have seldom penetrated; and others, in North Africa, where the local population is apparently exposed to an excess of virus throughout most of every year, and where immunity to both paralytic and alimentary infections is solid after the age of about 5 years. However, when poliovirus does penetrate into arctic areas and is given the opportunity to attack these highly susceptible "virgin" populations, we witness severe epidemics involving not only children but parents and grandparents as well. Indeed, it is the youngest group of children who apparently suffer the least under these circumstances. Such epidemics have been described on a few occasions in the Arctic, northern Canada,[4] and Alaska.[5]

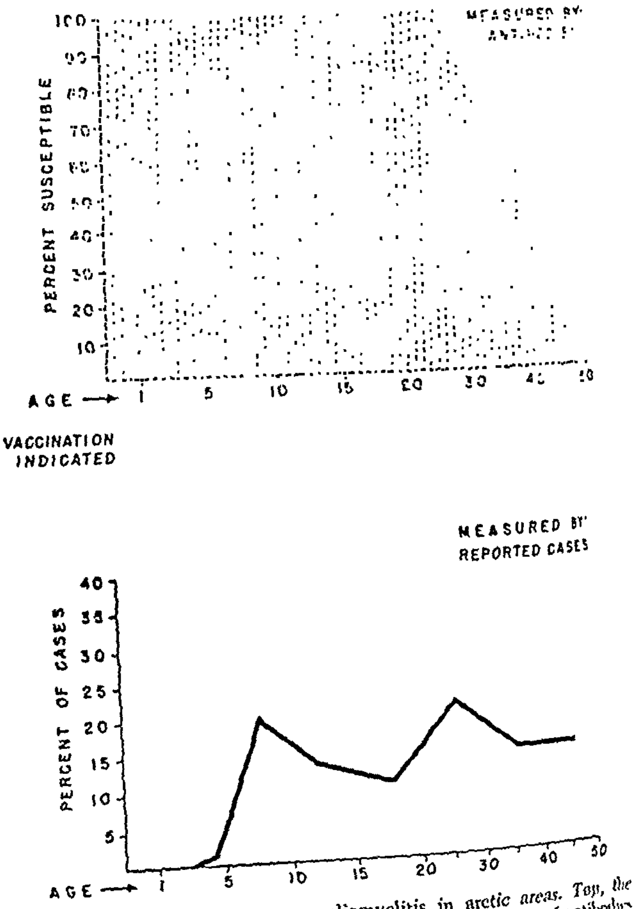

Fig. 2.—Status of immunity to poliomyelitis in arctic areas. *Top*, the period of susceptibility (vertical lines) as measured by a lack of antibodies to type 1 poliovirus. *Bottom*, the age distribution of cases in two of the rare arctic epidemics.

The status of immunity against poliomyelitis in a remote arctic population as estimated from series of clinical cases, and a serologic survey[6] is depicted in figure 2. What would be the routine indications for vaccination in an arctic population of this type? For the first antipoliomyelitis vaccination program to be carried out in such a population, probably everyone within the community should be vaccinated, old as well as young. Subsequently, owing to the infrequency with which polioviruses enter the community, it is possible that artificial vaccination of some kind might well be repeated in these areas every few years, if immunity is to be maintained. Decisions here might be aided by sequential antibody surveys.

To turn next to the opposite situation of the "immune population," such as is seen in populations in the Middle East[7] or North Africa,[8] or in others with comparable primitive living conditions, solid immunity comes early and 90% of the paralytic disease that does occur can be found in children under 5 years of age—the old-fashioned infantile paralysis (fig. 3). Serologic evidence through the use of the complement-fixation test also indicates that inapparent infections capable of inducing complement-fixing antibodies virtually cease soon after this age. This stands in great contrast to the situation in most parts of the United States as well as in the Arctic. There would be little need today to vaccinate children in North Africa or the Middle East, unless one restricted the priority group to the youngest children, representing those of the age group of 7 months to 3 or 4 years.

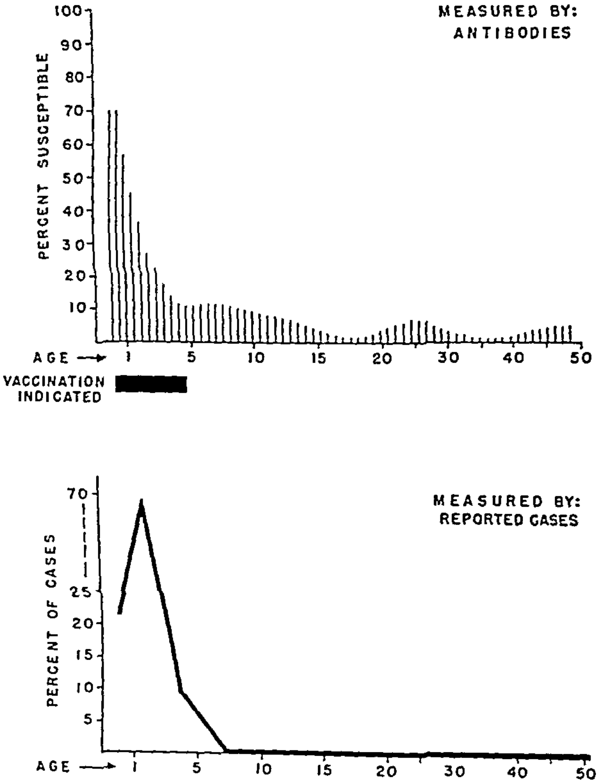

Fig 3 —Status of immunity to poliomyelitis in North African populations The percentage of adults without antibodies in such populations is small (*upper panel*), and when paralytic cases occur they are virtually confined to the youngest age groups

In the United States, there are all gradations of susceptibility and immunity. Not only do the poliomyelitis incidence rates vary geographically between northeastern, north central, and southern areas of the United States but the age distribution of acute paralytic cases within these regions also differs somewhat. Differences in the latter may exist between white and nonwhite populations. In some areas, such as the Latin-American population of three counties in southern Texas, there is a situation almost like North Africa and the Middle East[9]; in others, which represent some of our "best" areas, it is almost frighteningly like the Arctic.[10] The differences in the age distribution of poliomyelitis cases between these areas, surveyed more or less simultaneously (1948-1954), are as great as those separated in time by 40 years in Connecticut: the Hidalgo County, Texas, age distribution being similar to that of Connecticut in 1916, and others to that of 1955 (fig. 1).

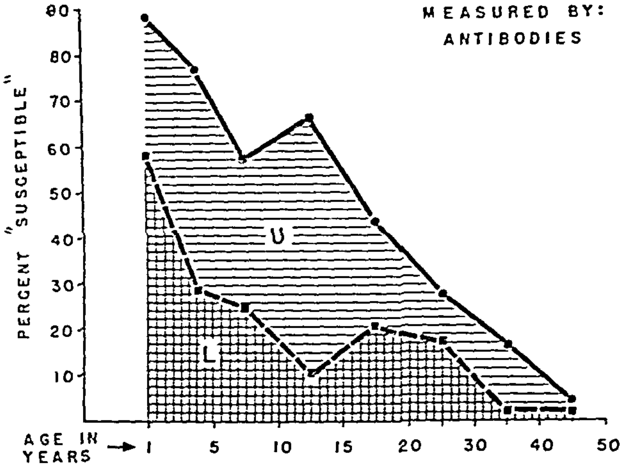

Fig 4 —Comparison of rates at which antibodies to poliomyelitis were acquired in two different socioeconomic groups, living in the same city, Charleston, W. Va U = upper socioeconomic group, L = lower socioeconomic group.

In the United States there are gradations within the same city. A population living in the poorest urban area acquires infection and gains its immunity to poliomyelitis early in life, that is in infancy; an urban or suburban population living in or near the same city, but in better quarters, acquires infection and gains its immunity later in life. Such intraurban observations have been carried out recently in Charleston, W. Va.[11] (fig. 4).

Antibody surveys, if done in the United States, should include the age groups from 18 to 30, for one of the disturbing features about the age incidence of paralytic poliomyelitis in this country today is the increasing frequency of adult cases, often in young parents. Young parents run the extra risk of being infected by their children, who may pick up the virus, perhaps in a nursery school, and as a result expose their parents, particularly their mothers,[12] to a heavier dosage of virus than the latter would ordinarily receive in the environment in which they live. The predominance of female cases in the group from 20 to 30 years of age may possibly be due to an increased susceptibility of pregnant women as well as to greater exposure. The increased rate of paralytic cases in this age group (fig. 1, 1955, and fig. 2), as well as the sex differences, demands more observation and study. Meanwhile indications for vaccinating young parents are appreciable.

instance even when all three types were fed simultaneously. However, a delay in appearance of antibody and titers in the lower range were observed in some of the men.

In the early stages of using a living attenuated poliovirus vaccine, it would be desirable to administer only one type at a time in order that one might have a better chance of identifying a paralytic disease due to spontaneous infection prior to ingestion of the vaccine. Accordingly, the feasibility of administering 100,000 ID of the optimum available attenuated strain of each type at three-week intervals was tested in 16 volunteers and found to be satisfactory. Although some of the volunteers stopped excreting one type of virus before the next type was fed, one pattern obtaining in those who were still excreting virus at the time of the next feeding is shown in figure 1. It can be seen that for a few days, occasionally as long as a week, both types of virus continued to be excreted before the new type became dominant.

Viremia.—In five to seven repeated tests for viremia on each of 50 chimpanzees and 72 human volunteers infected with various laboratory-developed attenuated strains of all three types, poliovirus was not demonstrated in a single instance during the preantibody phase of the infection. With several naturally occurring attenuated strains, transitory traces were occasionally found in the blood of both chimpanzees and human beings. These studies suggest that the viremia observed in nature and in champanzees and monkeys experimentally infected with virulent strains cannot be the result of viral multiplication in the alimentary tract and is probably due to multiplication elsewhere in the body.

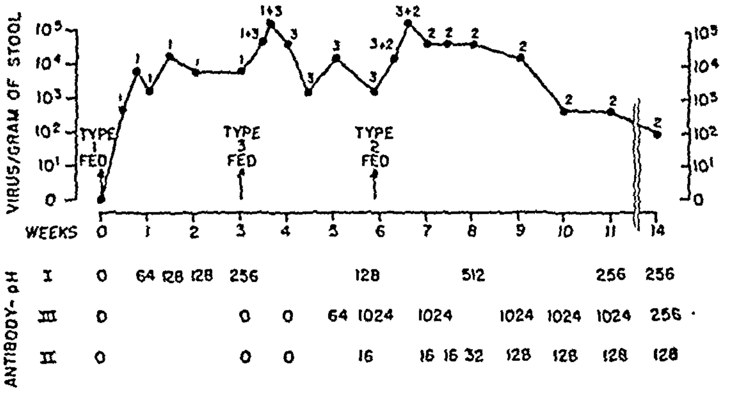

Fig. 1.—One pattern of virus multiplication in the human alimentary tract when 10^5 plaque-forming units of three immunologic types of attenuated poliovirus were fed at three-week intervals to an adult volunteer without antibody for any of three types of poliovirus. Numbers over dots indicate types of virus being excreted.

Antibody Development.—All alimentary infections have been associated with development of antibody, although the actual titers varied with the individual as well with the strain of virus. During the past year, Chanock and I found that neutralizing antibodies of different avidity appear at different times after natural infection with virulent strains, after experimental infection with attenuated strains, and after inoculation with formalinized vaccine. The antibody of low avidity, best demonstrable by the pH test, appears first and its titer can be more than 60 times higher than the antibody of high avidity demonstrated by the cytopathogenic test against 100 ID of virus in roller tubes. We have found a certain number of people with natural subclinical infections who have only the low-avidity antibody demonstrable by the pH test, and the same was also true of several volunteers infected with the type 1, L Sc strain or the type 3, attenuated Leon virus. Koprowski[2c] reported no significant change in titer of type 2 antibody in a group of 11 individuals 4½ to 5½ years after feeding of his original TN strain of reduced intracerebral virulence for monkeys. Our own tests on a group of 11 men one year after feeding one or another of three types of attenuated virus showed no significant change in the level of antibody, the low levels remaining low and the high levels remaining high.

Multiplication of Virus in the Alimentary Tract in the Presence of Antibody Acquired in Different Ways.—Bodian's experimental studies on monkeys and chimpanzees have shown that the alimentary tract can be infected in the presence of certain levels of passively transmitted antibodies.[10] Koprowski and his associates[11] showed that the low levels of antibody passively transmitted by small doses of gamma globulin or the higher levels of placentally transmitted antibody in infants did not interfere with the multiplication of attenuated type 1 or type 2 poliovirus in the alimentary tract. Howe's studies on 19 chimpanzees extensively hyperimmunized with formalinized vaccine indicated that alimentary infection was reduced by about 50% after feeding of virulent type 1 virus,[12] but these studies cannot be transposed to humans, since in champanzees the throat is the dominant site for infection and the throat secretions are known to contain antibody when the serum antibody level is

above a certain minimum. My own studies during the past year have shown a marked difference between the resistance of the alimentary tract to infection in those who have acquired their immunity by subclinical infection and those who developed antibody after two doses of Salk vaccine.

The data in table 3 show that neither the duration of virus excretion nor the peak virus titers per gram of stool were significantly different among the eight volunteers who were fed 100,000 ID of type 1 virus after two doses of Salk vaccine (the interval between the two doses was about four weeks, and the virus was fed two to three weeks after the second dose) and the 11 volunteers without antibody who were infected with the same dose of the same lot of virus. However, among eight volunteers with varying levels of naturally acquired antibody for all three types, there was no infection in seven. The data in table 4 show the lack of any relationship between the level of preexisting antibody, of low or high avidity, and the interference with viral multiplication in the lower alimentary tract. It is possible that the one naturally immune individual in whom the virus multiplied may not have had a previous type 1 infection, his very low level of type 1 antibody being the result of a group response to his type 2 or 3 infection. Similar results were obtained after feeding of type 2 and type 3 virus after two doses of Salk vaccine, but among the naturally immune controls virus multiplication also occurred in two of six fed the type 2 virus and in three of six who received the type 3 virus.

Reinfection tests on volunteers three months after experimental feeding of the type 3, attenuated Leon virus yielded similar results, and resistance of the alimentary tract to 1 million ID was observed in a volunteer who had only minimal amounts of low-avidity antibody. These results have a double significance. On the one hand they prove that subclinical infection can occur in those who have had formalinized vaccine and that it is possible to use a combination of the two types of vaccine, and on the other hand they indicate that a killed-virus vaccine alone may be expected to have little effect on the dissemination of polioviruses in nature. The latter conclusion is also supported by the observations of Lipson, Robbins, and Woods[13] and those of Gelfand and his associates[14] on the excretion of poliovirus under natural conditions of infection in children given Salk vaccine.

Neurotropism of Excreted Virus After Feeding of Various Attenuated Strains.—The most important question in these studies is whether attenuated viruses can become sufficiently more neurotropic after propagation in the alimentary tract to constitute a risk not only to the person who ingested the virus but to others to whom it might spread. It would be much easier to obtain the answer if we were dealing with an all or none property rather than with a spectrum of activity that can be measured only by quantitative tests in monkeys. Using extracts of the original stool, it is as a rule possible to inoculate only 100 to 10,000 ID, and a negative result indicates that the predominant virus population in the stool is attenuated to this extent, although here too paralysis of an occasional monkey may only reflect the capacity of the monkey nervous system to select a few more neurotropic particles from the larger inoculum. To permit more definitive tests, it has been necessary to increase the amount of virus by growing it in tissue culture before tests are made in monkeys.

* Naturally occurring strains

† Properties in parentheses eliminated strain

During the past four years, I have tested 40 chimpanzee and 68 human stools (in a number of instances several specimens from the same individuals) and the cultures derived from them for neurotropism in monkeys. The results were different with different strains, depending in part on how extensively attenuated the original virus was and how mixed the population that was fed. The results of these tests as well as those reported by Koprowski[2] in the tests he has carried out with his strains permit only the broad conclusion that reversion to high virulence has not been demonstrated and that the alimentary tract does not selectively favor more neurotropic poliovirus. Since the intestinal tract provides a large surface for viral propagation that can continue for many generations over a period of weeks, it is clear that the more mixed the original population and the more neurotropic the bulk of the viral population, the more frequently one may expect to encounter virus of greater neurotropism in the stools. This in fact occurred with the least attenuated Mahoney strain as well as with all of the naturally occurring type 1 attenuated viruses.

The indication that the alimentary tract does not selectively favor the more neurotropic particles was derived from observations that greater neurotropism of virus in the stools was a chance finding encountered in some and not in others, sometimes during the first two weeks and not later in the same individual and sometimes the reverse; i. e., *not in the early specimens* but in the later ones. In the one volunteer who excreted virus for 140 days after ingestion of the partly attenuated Mahoney strain, neither the original stool nor the culture fluid derived from it showed evidence of greater neurotropism at 140 days, although the 9-day stool specimen did. More highly neurotropic stool cultures that paralyzed monkeys after intracerebral inoculation of 10,000 ID were in three instances inoculated intraspinally in doses exceeding 1 million infective virus particles in nine chimpanzees without production of paralysis. Nevertheless, in selecting attenuated strains for further study, all those that even occasionally yielded stools or stool cultures that produced paralysis in intracerebrally inoculated monkeys at the 10,000 to 100,000 level were eliminated as being either too mixed or too neurotropic. Six of eight type 1 strains that I had tested in chimpanzess or in human volunteers or both (table 5) and Koprowski's type 1 (SM) strain [2] had to be eliminated on this basis, and only the most highly attenuated L Sc strain originally developed by Li and Schaeffer [8] and further purified in my laboratory proved to be satisfactory. The most suitable candidate for the type 2 strain was segregated from the stool of a healthy child that was sent to me by Drs. Fox and Gelfand of New Orleans and designated as P 712, and the type 3 strain that fulfilled these requirements was an attenuated derivative of the original Leon virus segregated in my laboratory.[3] The type 2 strains used by Koprowski and his associates [15] were eliminated chiefly because of their greater neurotropism.

Stability on Propagation in Large Lots.—The stability of these three selected strains on large-scale cultivation in monkey kidney was tested by preparing 20-liter lots of each. Various tests failed to reveal any simian cytopathogenic agents in these 60 liters of culture fluid. The intracerebral and intraspinal titrations in monkeys as well as the spinal tests in a total of 15 chimpanzees yielded results that were identical with those previously obtained with the seed lots. These lots were employed in 53 human volunteers, establishing among other things the effectiveness of 0.01 ml. of culture fluid (100,000 plaque-forming units) as a standard dose. Despite this demonstrated stability on large-scale cultivation, an analysis of a large number of individual virus particles, in the form of progeny from triply purified plaques, showed that the original seed viruses were not homogeneous and that still more highly attenuated viruses could be isolated.

Neurotropic Activity of Progeny of Individual Virus Particles Recovered from Optimum Attenuated Strains.—Data are summarized in table 6 concerning the neurotropic activity of the progeny of individual virus particles recovered from optimum attenuated strains. Reproducible spinal titrations in monkeys were obtained with cultures grown from the original type 3 seed virus in large or small amounts with virus inoculums of different size, but the progeny obtained from nine individuals particles yielded entirely different results. Three (plaques 7, 8, and 9) were distinctly more neurotropic, and four (plaques 3, 4, 5, and 6) were similar in activity to the parent population; two of the plaques yielded for the first time virus that in the largest doses was not paralytogenic in large numbers of monkeys. The results obtained with the type 2 virus showed a similar inhomogeneity, and the progeny from one of the nine plaques tested (plaque 1) was distinctly superior to all the others. Subsequent passages in cultures at a pH of 7.6 to 7.8 yielded virus that was nonparalytogenic in the largest doses. It should be pointed out here that these nonparalytogenic variants still have a certain minimal residual

neurotropism, for, while some of the monkeys show no specific lesions of any kind even in the gray matter adjacent to the inoculum, focal poliomyelitis lesions are present in others. These new single-particle strains have been fed to 10 chimpanzees, and they produced immunogenic alimentary infections in all.

The type 1, L Sc strain, which already possessed such low activity that monkeys inoculated intraspinally with 1 million ID only irregularly exhibited slight localized, often only transitory, paralysis also revealed somewhat different patterns among the progeny derived from 10 different plaques. Particularly noteworthy was the fact that the progeny of some of the virus particles (especially plaques 3 and 4) exhibited the zone phenomenon, while others did not. The zone phenomenon [3c] is characterized by the appearance of paralysis in monkeys inoculated with smaller doses and not with larger ones. The progeny of plaque 1, devoid of this zone phenomenon, was distinctly superior to all the others. Similar tests in monkeys with the progeny of 14 plaques from the two optimum naturally occurring attenuated type 1 strains (P 2149 and P 2226) showed that all of them were highly paralytogenic intraspinally at both the 1 million and 100,000 dose levels. Still another attempt to obtain type 1 virus that might be superior to that derived from the best L Sc plaque was made by an analysis of four individual plaques derived from a culture of human stool obtained 15 days after ingestion of the original L Sc seed virus. This stool culture had the same low activity intraspinally in monkeys as the progeny of the best L Sc plaque and was also devoid of a zone phenomenon. The viruses recovered from these four plaques were similar in their activity to that of the parent culture but not superior to the best L Sc plaque.

Relationship between Plaque Size and Neurotropism.—A definite relationship between neurotropism and plaque size in vitro has been found for the type 3 and 2 but not for the type 1 viruses. Under the special conditions in the rubber-stoppered plaque bottles prepared by the technique of Hsiung and Melnick,[16] the smallest plaques were produced by the most highly attenuated strains. Figure 2 shows the sizes of plaques at the same time after inoculation of the original highly virulent type 3 Leon virus, of the attenuated derivative segregated from it after many passages in monkey-kidney cultures, and of the nonparalytogenic progeny of the two particles that were in turn segregated from it.

Relationship Between pH of Culture Medium and Yield of Virus by Virulent and Attenuated Strains.—During the course of our work with various attenuated strains, it was observed that the yield of virus was at least tenfold less when they were propagated in tissue cultures that had metabolized sufficiently to reduce the pH of the medium to 6.8 or less. Dulbecco and Vogt,[17] working with strains of known neurotropism from my laboratory, recently discovered a distinct relationship between neurotropism and plating efficiency on acid and alkaline plates. They found that, while the virulent viruses yielded as many plaques on the acid as on the alkaline plates, the more attenuated the strains were the fewer plaques they produced on the acid plates at a given time after inoculation. These differences (as high as one-million-fold) were most marked with our newly isolated single-plaque strains. Tests that I carried out (table 7) showed that, while with virulent strains the yield of infective virus per cell was only slightly greater at pH 7.8 (high bicarbonate reserve) than at pH 6.8 (low bicarbonate reserve), it was six-to-eight-fold less at pH 6.8 for the most highly attenuated single-plaque strains. This means that propagation at an acid pH would favor the more neurotropic mutants that might emerge, and conversely that propagation at an appropriate alkaline pH would prevent the enrichment of such mutants in the culture medium.

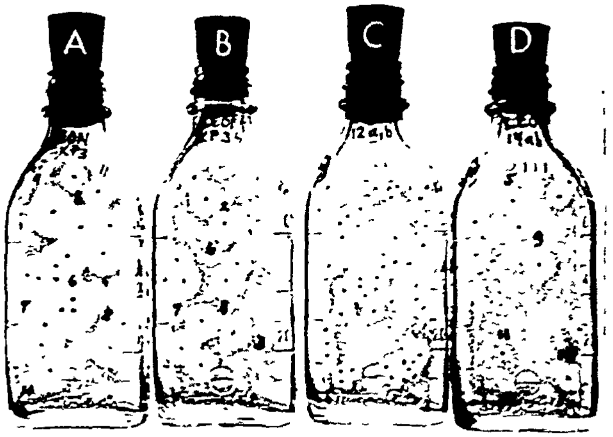

Fig. 2.—Relationship between size of plaques on a given day after inoculation and neurotropism in cynomolgus monkeys of virulent type 3 parent poliovirus and attenuated progeny segregated from it. All plaques were grown at the same time and photographed five days after inoculation. *A*, plaques highly virulent intracerebrally. *B*, inactive at 10^6-10^7 intracerebrally, intermediate activity intraspinally. *C* and *D*, purified plaque progeny isolated from Leon, KP_{34}. Not paralytogenic intraspinally in doses as high as 6 million plaque-forming units. Different size of plaques in same bottle may only reflect different day of first appearance.

Comment

It may be said that much has been learned about the basic principles underlying immunization with attenuated polioviruses by the oral route and that we now have strains derived from single particles of virus that are sufficiently highly attenuated and stable under appropriate conditions of cultivation to justify their use for the next stepwise studies on immunization of human beings. Experience has taught me the importance of accentuating the negative, and I therefore wish to stress that we are not ready for so-called mass trials of an orally given vaccine but only for those tests on increasingly larger groups that must precede any consideration of tests on a large scale. I also want to accentuate the positive by saying that the Salk vaccine is the only poliomyelitis vaccine available for public use at this time and that advantage should be taken of its protective effects to the maximum extent of its availability. I may add that some of my earlier reservations disappeared with the demonstration that the antibodies and immunity produced by the Salk vaccine do not interfere with the alimentary infection produced by an orally given attenuated vaccine or naturally acquired virus. This then is as far as we have gone, and it is obvious that we still have a great deal to learn before the ultimate goal of complete elimination of poliomyelitis is achieved.

Elland Avenue and Bethesda (29).

The following fellows-in-training and associates assisted in this study at different times and for different periods during the past four years: G. Berg, M. Bornstein, R. M. Chanock, V. Drouhet, H. Gerth, W. A. Hennessen, D. Laron, G. Lum, C. Moscovici, H. Nakai, M. Ramos-Alvarez, A. J. F. Schwarz, and S. S. Wang.

This study was aided by a grant from the National Foundation for Infantile Paralysis.

CONSERVATIVE THERAPY IN PERIPHERAL NERVE DYSFUNCTION

Keith C. Keeler, M.D., Akron, Ohio

• *The mechanical properties of nerve fibers and the changes they undergo during and after mechanical strains are well understood. This knowledge affords a factual basis for the diagnosis and treatment of peripheral nerve dysfunction, as is illustrated by a detailed description of the physical therapy applied in a case of neuropathy of the facial nerve. The aim is to stimulate the contractile elements of muscle temporarily denervated, retain extensibility of fibrous tissues in and about the muscle, maintain elasticity of the capsule about affected joints, promote increased blood supply, and insure good position and motion of the affected part during the recovery period. Electrical stimulation, passive motion, assistive exercises, and dynamic bracing are important. Electromyography gives valuable information and can be used to motivate the patient. Exercise, to be effective, should be against sufficient resistance and should continue until the parts involved have regained strength in proportion to the demands of the patient's occupation.*

When a peripheral nerve is injured, it attempts to regenerate. The management of a peripheral nerve injury consists of providing the most favorable conditions for return of function. In commenting upon a paper by Perret in 1950, Loyal Davis[1] said, "More attention should be paid to keeping the muscles and joints in condition by all types of physical therapy and electrotherapy, so that, when the nerve does regenerate, the affected mechanism can work." Many factors cause peripheral nerve dysfunction, the most common being trauma; but anoxia[2] and infections such as herpes zoster[3] also occur. Assuming the etiology is known, management of the denervated motor elements and joints during the period of absent voluntary function must be based on pathophysiological conditions; thus, a review of some of these conditions is important.

Pathophysiology

According to the reaction of degeneration test, a denervated muscle fiber responds only to frequencies below 25 stimuli per second and chronaxy is lengthened; electromyographic studies show irregular spontaneous fibrillation potentials between 5 and 10 mv., which represent involuntary contractions by individual muscle fibers. No electrical potential is elicited by electromyography on attempted voluntary contraction in a denervated muscle. Studies of the gross muscle bulk during an extended period of denervation muscle atrophy show a loss of total substance.[4]

Chemical studies, particularly by Hines,[5] have indicated that this gross muscle atrophy indicates a reduction of the muscle-cell phase, in both absolute and

---

Read before the Section on Physical Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

relative volume, whereas the non-muscle-cell phase undergoes an increase in relative volume, with no change in absolute volume. The chemical composition of atrophic muscle fibers is essentially the same as in the normal with respect to many constituents; however, certain substances such as glycogen show a decrease in concentration quite out of proportion to that attributed to mere reduction in volume. In his studies on the rat, Hines showed that in a normal muscle about 14% of chemical composition is attributed to the extracellular constituents and about 86% to the muscle cells. After 28 days of denervation in these rats, the total of chemical constituents is about 23% of the normal muscle, in which 50% of the chemical constituents comprise the muscle cells and 50% the non-muscle-cell substances.

Microscopic studies by Shaffer[4a] and his collaborators, Gutmann and Guttmann,[4b] and Adams, Denny-Brown, and Pearson[4c] demonstrate that, during muscle atrophy, fibers degenerate at irregular rates within a single muscle; there are areas of swelling of cytoplasm, cellular infiltration, vacuolation, and hyalinization. Bowden and Gutmann[6] found that irreversible dysfunction of muscles was associated with shrinkage of myofibers, relative increase of connective tissue, progressive depletion of cytoplasm at the motor end-plate, and progressive disturbance of vascularization. Thus, the muscle is in such a state after about three years that functional recovery will not occur despite reinnervation.

The effects of trauma to the nerve were studied by Denny-Brown[7] who reports that percussion of a nerve will produce a localized bulge associated with transient partial or complete paralysis and peripheral degeneration, according to the intensity of the blow. Regeneration tends to be rapid and complete. Kneading a nerve produces a severe intraneural hemorrhage that resolves rapidly until full function is restored. In a cat peroneal nerve, Denny-Brown demonstrated that a segment of this nerve could be stretched 100% of its length and that it exhibited a plastic effect, wherein the nerve tended to remain in the elongated position. Further stretch of the nerve caused petechial perineural hemorrhages, neural edema, dilated veins, and fibrosed and thrombosed arterioles. With violent stretching, the neurilemma tended to split longitudinally, producing herniation of fiber material; finally, with maximum traction, the neurilemma and its contents frayed into complete loss of continuity. He observed further that large nerves like the sciatic would not stretch as much as smaller nerve divisions, there being an inverse relationship between nerve diameter and elasticity.

In his studies on nerve repair, Hoen[8] reports, "A poor vascular bed for repaired nerve fosters the development of fibrous tissue." Further observation was made by Hoen relative to technical problems in joint motion and stretch of nerves across joints.[4d] Hoen agrees with Denny-Brown in that the central portion of a severed nerve that has normal structure and normal blood supply may be stretched under gentle and prolonged traction because it has normal ability to withstand stress and strain. It is further interesting to note from Hoen's studies that, in those cases wherein the distal section of a nerve stump had been inadvertently sutured to a central tendon, the constant traction on these nerve stumps caused complete fibrosis of the entire distal section of the nerve.

With respect to electrical stimulation, the literature is replete with scientific data compiled to justify[9] and refute[10] its efficacy. Most investigators of the effects of electrical stimulation on peripheral nerve damage concentrated their attention on muscle tension, while Wakim[9c] introduced the significant fact that blood flow is increased by electrical stimulation but bears no relationship to the characteristics of the current used. Nevertheless, from the studies of Bowden and Gutmann,[6] Osborne,[9d] Gutmann and Guttmann,[4b] and Shaffer and his co-workers,[4a] it can be concluded that muscle atrophy can be retarded by electrical stimulation providing (1) therapy begins early, (2) treatment is performed at frequent intervals, and (3) muscles under stimulation contract against resistance.

Having the benefit of such pathophysiological studies, the attending physician approaches the management of a case of peripheral nerve dysfunction by determining (1) etiology, (2) extent of injury, (3) appropriate specific surgical or chemical therapy, and (4) appropriate physical therapeutic measures to maintain optimum physiology of the affected part.

Therapy

Physical therapeutic measures are conservative in application but dynamic in effect, for they (1) stimulate the contractile elements of muscle during denervation, (2) retain extensibility of fibrous tissues surrounding each muscle fiber and fasciculus of fibers, (3) maintain elasticity of the capsule about affected joint, (4) promote increased blood supply, and (5) provide functional alignment and partial usage of the affected part during the denervation and recovery period.

The application of specific techniques of conservative therapy for neuropathy of the facial nerve (Bell's palsy) and for involvement of the nerve in an extremity is discussed below. It is assumed that the correct etiology has been established and proper surgical and/or drug management followed.

Neuropathy of Facial Nerve.—In neuropathy of the facial nerve, the patient is advised to keep the face warm by giving himself mild heat treatments for 15 minutes three times daily. If he goes outdoors in wind or cold temperature, he should protect the side of the face involved by a scarf or collar. He is also instructed to rinse his mouth after each meal and to rinse the eye on the affected side with isotonic sodium chloride solution twice daily or after exposure to air dust when out of doors. At these times, a patch over the eye is advisable. He is instructed to place a strip of cellophane tape, or adhesive tape, on the affected side of the face from the corner of the mouth to just in front of the ear. He begins by putting the tape on at the corner of the mouth, pulling the mouth upward and wrinkling the cheek, and fastening the other end of the tape in front of the ear. This pressure keeps food from getting lodged in the cheek and also minimizes the drooling of liquid out of the corner of the mouth on the affected side. Furthermore, such functional splinting prevents stretching of these small, denervated facial muscles that, being subjected to gravity forces, allow a sagging of the cheek and corner of the mouth.

Electrical stimulation by galvanic current is then prescribed. A voltage that produces the maximal muscle contraction tolerable is therapeutic, because it provides optimum summation of muscle fibers. The side of the face that is to be stimulated is generally preheated for 10 or 15 minutes with a mild infrared or radiant heat lamp. This reduces skin resistance and permits use of less voltage to obtain the same contraction. I prefer a surging, or sinusoidal-type, galvanic current at a rate of 20 stimuli per minute, which allows a rhythmical muscle response with each stimulus. Daily treatments of 15 to 30 minutes' duration are initially prescribed. In children under 12 years of age, electrical stimulation is not satisfactory because the voltage tolerated by the child is of so slight a magnitude that contraction seldom results. Fortunately, the period of motor dysfunction in neuropathy of the facial nerve in children is relatively short.

As one proceeds in therapy, faradic current is tried periodically to ascertain the first evidences of reinnervation. A response to faradic current is heralded by the observation that less galvanic current is required to give the same magnitude of contraction as originally necessary in the treatment. An alternating, or faradic, current of 200 to 1,000 impulses per second may eventually be used and will, in many instances, be more comfortable for the patient. Electrical stimulation is reduced in frequency with the advent of reinnervation. As traces of voluntary movement appear, the patient can exercise his own facial muscles; the frequency of supervised treatment, therefore, is reduced to once or twice weekly until it is felt maximum return of function has been achieved or is imminent.

Peripheral Nerve Dysfunction in an Extremity.—In treatment of peripheral nerve dysfunction in an extremity, the prescription calls initially for passive motion of the joints affected by the nerve dysfunction in order to maintain elasticity of the periarticular structures. This is gently carried out through full range and in all directions of joint movement.

Dynamic bracing to permit as much normal function as feasible has been well described by Von Wersowetz and co-workers,[11] Shields and Smith,[12] and many others. Dynamic bracing, as opposed to static splinting, offers the following benefits: It (1) retains a functioning extremity; (2) maintains circulation in the extremity through muscle action; (3) permits partial joint motion; and (4) permits involved muscles to be lengthened and contracted passively or assistively, as nonaffected muscles perform their normal function.

Electrical stimulation of denervated muscles is prescribed in the same general manner as described for neuropathy of the facial nerve. Though artificial, it is presently the only method available therapeutically for reproducing controlled muscle shortening in the absence of nerve supply. In an extremity it is advisable to use a voltage that gives maximum contractile response in the stimulated muscle and visible movement at the joint across which the affected muscle acts. Contraction against the resistance of 2-to-5-lb. weighted sandbags will provide a greater recruitment of muscle fiber. Osborne,[9a] presented data indicating that atrophy occurring prior to onset of electrical stimulation was not reversed.

As increasing motor units within a muscle are reinnervated, supportive aids such as electrical stimulation and passive motion are supplanted by assistive exercises. In my experience, inserting needles from the electromyograph into partially denervated muscles helps the patient exercise those fibers that will voluntarily respond. The wave frequency and height of oscillations on the oscilloscope give him visual evidence of muscle activity. The crackling of the loud-speaker adds auditory evidence. With additional motor units brought into action by increased effort, more waves occur on the oscilloscope; the sound of muscle contraction over the loud-speaker resembles that of a mechanical motor. The motivational effect on men and boys, especially, is profound. Electrical stimulation may be continued occasionally during this transition period until the part can be moved actively on the powder board. Progressive increments of weights used add friction, thus demanding maximum response from existing motor units.

Exercise with graduated resistance against gravity continues the process of demanding maximum response from active motor units as more muscle fibers are reinnervated. Exercises are continued until optimum strength and coordination are obtained, depending upon requirements of the involved parts in relation to the patient's employment. For instance, the serratus anterior of a plasterer requires more strengthening than that of a cashier. It is important, therefore, to pursue therapy until the muscle requirements of the patient's job are met.

Summary

Conservative therapy in peripheral nerve dysfunction is auxiliary in character but promotes optimum circulation, contractility, and elasticity of motor elements and minimizes secondary pathology associated with joint immobility and intramuscular fibrosis during the denervation period.

SUBTOTAL GASTRECTOMY WITH AND WITHOUT VAGOTOMY FOR DUODENAL AND GASTROJEJUNAL ULCER

PRESENT STATUS

Ralph Colp, M.D., New York

• ***Subtotal gastrectomy alone was done in 224 patients and combined with infradiaphragmatic vagotomy in 217 patients who had duodenal and gastrojejunal ulcer. Of the three operative deaths, two were in the latter group but could not be ascribed to the vagotomy. Of the 17 proved instances of recurrent peptic ulcer disease, only one was in the vagotomized group. Vagotomy entailed an increase in postoperative morbidity and a risk of prolonged moderate diarrhea, but it afforded some protection against subsequent jejunal ulceration.***

Gastroenterostomy was done in 101 patients, with vagotomy in 70 of these. The rate of recurrences was 15% in the patients without and 10% in the patients with the vagotomy. It appeared that vagotomy afforded little protection to the patients with gastroenterostomy. A continuation of the subtotal gastrectomy of the Billroth 2 type, preferably combined with vagotomy, is recommended on the basis of this experience.

During the past decade, there appears to have been less reluctance on the part of the general practitioner and gastroenterologist to advise surgery for patients suffering from the complications of chronic duodenal ulceration. Many intelligent patients, becoming cognizant of the recurrent nature of the disease and its impact upon their social and economic life, are demanding operation. This change in attitude has not been fortuitous. The profession undoubtedly has been influenced by the lowered morbidity and mortality and the excellent results of gastric resection, and some sufferers from peptic ulcer have been swayed probably by the publicity accorded the "nerve operation," which for a time was a recurrent theme in the daily press. That there has been a renewal of interest in vagotomy as a complementary procedure in both gastroenterostomy and subtotal gastrectomy and as a supplementary one in the alleviation of gastrojejunal ulcer is quite apparent from the plethora of articles appearing in most medical journals.

This communication is concerned with (1) a few technical considerations that I believe to have been responsible for the lowered mortality and morbidity of subtotal gastrectomy, (2) the present status of this procedure with and without complementary vagotomy, and, briefly, (3) the effect of supplementary vagotomy upon gastrojejunal ulceration.

Operative Technique and Surgical Indications

For the past 30 years, I have considered subtotal gastrectomy of the Billroth 2 type the procedure of choice in the treatment of chronic duodenal ulcer. The operative technique at present is basically the one developed by the late A. A. Berg and R. Lewisohn, in which two-thirds to three-quarters of the stomach is removed, with gastrointestinal continuity restored by terminolateral gastrojejunostomy of the Hofmeister type. However, during the years my associates and I have made many changes, both in technique and in clinical approach, all designed primarily to lessen postoperative morbidity and mortality.[1] The improvements in anesthesiology and in preoperative and postoperative care, especially the correction of electrolyte imbalances, the maintenance of blood volume, and the use of antibiotics, need no comment.

The greatest hazard of subtotal gastrectomy of the Billroth 2 type is still the possibility of perforation of the duodenal stump with the development of fatal peritonitis. Many of these accidents can be prevented or their seriousness diminished by certain simple prophylactic precautions. In penetrating ulcers of the posterior wall or those situated in the second portion of the duodenum, removal of the lesion may entail injury to the common bile duct, the head of the pancreas, or the accessory pancreatic duct (duct of Santorini), leading to grave postoperative complications. This type of lesion should therefore be left alone. Removal of the ulcer is not an essential part of the operation as long as the pylorus and antrum have been completely resected. An ulcer left in situ is rarely the cause of immediate postoperative complications, and, moreover, it bears no relationship to the occurrence of subsequent gastrojejunal ulceration; in the majority of the patients in this series who developed subsequent gastrojejunal ulceration, the original ulcer by chance

---

From the Surgical Service of the Mount Sinai Hospital.

Read before the Section of Surgery, General and Abdominal, at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956 had been completely or partially removed. If the closure of the transected duodenum has been attended with difficulty and if there is an iota of doubt as to the security of the suture line, the area should be adequately drained, preferably through a right subcostal stab wound. In addition, the duodenum should be decompressed by the passage of a gastric tube through the gastroenteric stoma well into the afferent jejunal loop. I have never found it necessary to substitute a duodenostomy for a complete closure of the duodenum. (Personally, I would rather close a duodenum completely and anticipate the possibility of a duodenal fistula with a sump drain to which continuous suction could be applied, if necessary, than create one at the time of operation.)

Since 1937, gastrointestinal continuity has been restored routinely by an antecolic anastomosis of the Hofmeister type, with use of a short efferent jejunal loop. In addition to being perfectly satisfactory, this method is technically easier and has eliminated the danger of injury to the middle colic artery and the possibility of obstruction due to a prolapse of intestinal loops into the lesser omental sac, two possible complications in the performance of a posterior retrocolic gastrojejunostomy. Moreover, the separation of the anastomosis in the event of gastrojejunal ulceration presents few difficulties.

TABLE 1.—*Operative Mortality in 542 Patients*

Operation	Patients, No.		Deaths No.	Deaths %
Gastroenterostomy	28	101	5	5
Gastroenterostomy and vagotomy	73			
Subtotal gastrectomy	224		1	0.4
Subtotal gastrectomy and vagotomy	217		2	0.9

During the course of years, I also altered my clinical and surgical approach to several problems. It soon became apparent that hospitalized patients recuperating from the effects of a severe hemorrhage should never be operated on within a short time after their hemoglobin level and red blood cell count had been restored to normal; when they were, the operative mortality was considerable. These patients are now discharged for convalescent care for a period of at least six weeks, after which elective surgery may be performed with a minimal risk. Massive hemorrhages from a proved duodenal ulcer are rarely treated as surgical emergencies. Bleeding in most of these cases will cease spontaneously. If, however, after adequate blood replacement during a period of 24 to 36 hours, blood is lost as rapidly as it is transfused, immediate operation is indicated, as it also is in patients who apparently have stopped bleeding for a few days and then suddenly begin to hemorrhage again.

It was soon realized that not all patients would tolerate the magnitude of a gastric resection. If the operative mortality is to be kept at about 1%, a lesser surgical procedure must be substituted in selected cases. Gastroenterostomy, in spite of valid objections to it, was performed in about 18% of cases from 1946 to 1952.[2] It was used in 12 patients to evaluate the procedure. The remainder consisted of patients over 60 years of age who appeared physiologically older; those with severe diabetes; with chronic and advanced cardiovascular, pulmonary, nephritic, hepatic, or neurological diseases; and those who were extremely obese. Gastroenterostomy was also performed in patients in whom extensive edema and massive local infiltration would make a resection extremely difficult technically. Many experienced surgeons do not consider it a blow to their ego or a surrender of their technical ability or facility if a gastric resection is not performed because of severe systemic disease or local contraindications.

There were five deaths in this series of 101 patients undergoing gastroenterostomy. In 70, a complementary infradiaphragmatic vagotomy was performed. This high mortality for a simple procedure confirms the preoperative opinion that some of these patients probably would not have withstood the added trauma of a gastric resection. That I often made mistakes in judging the ability of patients to tolerate a major procedure is also true, because three in this group subsequently survived a subtotal gastrectomy for gastrojejunal ulcer.

Perhaps I have been a little too conservative in my surgery. I was probably lulled into a false sense of security by the hope that the addition of a vagotomy to a gastroenterostomy would materially lessen the incidence of gastrojejunal ulceration. I, as well as others, have been sadly disillusioned in this regard. In my experience, a small one to be sure, there has been to date a recurrence rate of 10% in patients with gastroenterostomy with a complementary vagotomy and 15% in those with gastroenterostomy alone. Yet some surgeons, whose results are obviously better, routinely choose gastroenterostomy and vagotomy for all patients with duodenal ulcer, reserving subtotal gastrectomy for those who subsequently develop gastrojejunal ulcer. However, I agree with those who feel that gastroenterostomy with vagotomy is indicated only in the poor-risk patients or when local conditions demand a conservative approach. In these instances it would appear illogical to employ the more hazardous operation of resection simply to improve upon the 85% expectancy of a good result with gastroenterostomy (preferably with vagotomy) if the patient survives.

Subtotal Gastrectomy With and Without Vagotomy

During the same period, 1946 through 1952, in which 101 patients were treated by gastroenterostomy, with or without vagotomy, subtotal gastrectomy of the Billroth 2 type was performed in 441 patients with chronic duodenal ulcer (table 1).

This procedure has always had its critics. They have stated that, in the hands of the average surgeon, the mortality is high and the end-results do not justify the magnitude of the procedure. These statements have been repeatedly refuted by the published records of many clinics. It is true, however, that in a small percentage of patients results are unsatisfactory. Some are rendered temporarily uncomfortable, others fail to gain weight due to nutritional disturbances, and a few are troubled by the dumping syndrome or diarrhea. A certain number will develop gastrojejunal ulceration. This latter complication, which is distressing and serious, has been reported in from 3 to 9% of the cases and often occurred in spite of the fact that the gastric resection was adequate and correctly performed. In these cases, high levels of free hydrochloric acid are usually present in the gastric aspirate. It became evident early in the experience of this clinic that the suppression of the chemical or hormonal phase of gastric secretion by resection did not always protect the patient against gastrojejunal ulceration.

TABLE 2.—*Length of Follow-Up of 390 Patients*

As early as 1927, Klein[7] conceived the idea of combining gastric resection with partial vagotomy in order to eliminate a second pathway to acid production, *i. e.*, psychic stimulation. With this combined method, he hoped to increase the incidence of achlorhydria, for, "no free acid, no ulcer." Subsequently, the follow-up results in 34 selected patients with high preoperative acidity in whom subtotal gastrectomy was combined with partial division of the vagus fibers on the anterior wall of the stomach seemed to verify Klein's contention.[4] In 1946, after the renewal of general interest in vagotomy as a definitive and sole procedure in the treatment of duodenal ulcer, I decided to combine subtotal gastrectomy with bilateral infradiaphragmatic vagotomy, provided the operative mortality and postoperative morbidity were not appreciably altered. At first, this combined procedure seemed especially indicated in the patients with duodenal ulcer in whom bleeding was the predominant symptom and those in whom preoperative acid levels were unusually high, two types of patients in whom jejunal erosions and ulcerations are most apt to occur. Subsequently, the indications were broadened, and, at present, the combined procedure is preferred whenever possible. However, in none of these cases has the extent of resection been lessened. I am not performing hemigastrectomy as yet.

The immediate postoperative results in 224 patients undergoing subtotal gastrectomy alone (group 1) and 217 undergoing the combined procedures of subtotal gastrectomy and infradiaphragmatic vagotomy (group 2) have been analyzed in detail in previous communications.[5] It may be stated briefly here that, postoperatively, there was a greater incidence of pulmonary complications, gastric retention, and vomiting and diarrhea after the combined procedure, but none of these proved serious. Three of the 441 patients died, one of them in group 1 and two in group 2, but none of these deaths was related to the vagotomy. Postmortem examinations revealed pancreatitis and bronchopneumonia in one, a massive pulmonary embolus (occurring on the second postoperative day) in the second, and necrosis of the body and tail of the pancreas in the third patient, who died on the 42nd postoperative day.

Follow-up of the patients in this series now covers one to nine years (table 2). During this period, there were seven deaths in group 1: one after 3 months due to a secondary resection for gastrojejunal ulcer; one after 10 months from an unknown cause; one after three years from carcinoma of the lung; three after four, five, and six years, respectively, from uremia; and one after seven years from a metastatic carcinoma of the brain. In group 2, there were four deaths: one after four months from homologous serum jaundice; one after six months from internal injuries incurred in an automobile accident; one from coronary thrombosis after a year; and one from cerebral hemorrhage after four years.

Follow-Up Results

The follow-up results have been classified as satisfactory or unsatisfactory, as judged by both the examiner and the patient (table 3). There are two types of patients with satisfactory results, the well and the improved. The former group includes patients who were well at all times after operation as well as those who had symptoms during convalescence or earlier follow-up but who were asymptomatic at the time of their last visit. The patients considered improved are those whose ulcer disease is apparently cured but who do have minor distressing symptoms. The unsatisfactory cases are those in which there have been proved jejunal ulcers or in which such lesions have been suspected. An "unclassified" group consists of those patients with symptoms and disturbances of gastrointestinal function sufficiently severe that the result can be labeled unsatisfactory but with no subjective or objective evidence of recurrent ulcer disease. There were two such patients in group 1 and three in group 2. All five suffered pain of moderate severity as well as either diarrhea, vomiting, or a mild dumping syndrome. Repeated careful examinations and x-ray studies failed to disclose the cause of these symptoms. One of these patients had a severe psychoneurosis.

TABLE 3.—*Results of Follow-Up of 390 Patients*

Results	Subtotal Gastrectomy No.		Subtotal Gastrectomy %		Subtotal Gastrectomy with Vagotomy No.		Subtotal Gastrectomy with Vagotomy %	
Satisfactory		184		90		179		97
Well	171		83		156		85	
Improved	13		7		23		12	
Unsatisfactory		21		10		5		3
Gastrojejunal ulcer	16		7.7		1		0.5	
Suspected ulcer	3				0			
Unclassified	2				4			

In group 1, of the 206 patients followed, results are satisfactory in 184 (90%) and unsatisfactory in 21 (10%). Of the patients with unsatisfactory results, 16 have had proved recurrences and 3 have had suspected recurrences, without hemorrhage, manifested by pain in one and a mild melena reported by the patient in 2. X-ray examinations in these patients were negative. There were two patients with side-effects, manifested by pain. In group 2, of the 184 patients followed, 179 (97%) are well, while of the 5 patients with unsatisfactory results, one has had a proved recurrence and 4 have had side-effects. One of these patients has a persistent and incapacitating diarrhea, and in the other four abdominal pain is present but the x-ray examinations are negative. Of the patients with results classified as satisfactory, six in group 1 and nine in group 2 had experienced a mild dumping syndrome. It may be surprising that we have observed no patient in whom there was a persistent and severe dumping syndrome, manifested by tachycardia, weakness, flushing, and fulness after meals. Many patients noticed an intolerance to milk and sweet drinks, but by eliminating these from their diets they were able to control their postcibal symptoms.

In the patients with proved recurrent peptic ulcer disease (16 in the group undergoing gastrectomy and one in the group undergoing gastrectomy and vagotomy), the presence of the ulcer was proved by either operation or x-ray examination or else was strongly suggested by massive gastrointestinal hemorrhage. Such bleeding may occasionally be the result of peristomal gastritis, erosions, or jejunitis, but it is most frequently due to actual jejunal ulceration. In any case, the operation that does not protect the patient from massive hemorrhage must be considered a failure. In this series, it has been considered evidence of recurrent ulceration and hence of an unsatisfactory result. The results in the patients undergoing gastrectomy alone are in very marked contrast to those in patients undergoing both gastrectomy and vagotomy, in whom, up to the time of writing, there has been but one recurrence. This occurred in a patient in whom, at the age of 18, a very high subtotal resection was done. Four years later, in 1952, a huge gastrojejunal ulcer developed that necessitated a total gastrectomy. When seen in 1955, the patient was well, without any side-effects.

A comparison of the results of the postoperative test meals showed that, regardless of the contents of the test meal or the time interval after operation, gastrectomy with complementary vagotomy consistently produced a higher percentage of patients with gastric anacidity than did gastrectomy alone. It would appear from these results that complementary vagotomy performed with subtotal gastrectomy in the surgical treatment of duodenal ulcer afforded added protection against recurrent disease at the cost of an increase in the postoperative morbidity and of a prolonged moderate diarrhea in about 10% of the cases; however, in only one patient was this diarrhea incapacitating. There is an impression that the undesirable side-effects of vagotomy do not justify its use and, moreover, that vagotomy should be reserved for the small percentage of patients in whom recurrent disease develops after gastrectomy. Twenty patients who developed gastrojejunal ulcer after subtotal gastroenterostomy were subsequently treated by supplemental vagotomy at this clinic; about 40% of the patients were not permanently benefited.[6] This simple procedure usually produced an immediate dramatic disappearance of the lesion, but ultimately the jejunal ulceration often recurred. It would seem that the best procedure in cases of gastrojejunal ulcer after a gastroenterostomy is not vagotomy alone but rather a high subtotal resection combined with vagotomy. Moreover, one should never expect vagotomy alone to be effective in treatment of a gastrojejunal ulcer occurring after subtotal gastrectomy if the previous resection has been inadequate or if the stoma has become obstructed. This type of case requires an additional resection, the correction of mechanical difficulty, or both.

There is also a group, fortunately small, of patients who have undergone subtotal gastrectomy in whom, regardless of the extent of the secondary gastric resection, even if combined with a complete vagotomy, unneutralized free acid is still secreted in large amounts and ulceration recurs. In the past, a total gastrectomy was the only effective remedy for this type of patient, and it was always performed reluctantly. I say "reluctantly" because most patients with total gastrectomy are not happy and suffer nutritional disturbances that require medical care throughout their life. Recently, Zollinger and Ellison[7] reported two instances of jejunal ulceration associated with hypersecretion and hyperacidity in which recurrent ulceration followed standard surgical therapy in both cases, finally necessitating a total gastrectomy. In each patient, nonspecific islet-cell tumors of the pancreas were eventually found. Certainly, in cases of this kind a careful search for individual tumors or even resection of the body and tail of the pancreas should be considered before a total gastrectomy is performed as a means of controlling secretion of free acid.

At the time of writing there is a wave of enthusiasm for revival of the Billroth 1 procedure, now often combined with vagotomy. Certain claims are made for its superiority because it has been stated that patients are able to maintain or gain weight, the incidence of the dumping syndrome is presumably lower, and there is, of course, no gastrojejunal ulceration. The latter is certainly true, but there are other possible complications, such as stenosis at the anastomosis and recurrence of duodenal ulcer. I shall reserve decision on the future usefulness of this procedure until subsequent follow-up statistics have been reported after an adequate period of observation.

Summary

As I reflect upon my experience over 30 years, I can state that, at present, results seem to justify a continuation of the subtotal gastrectomy of the Billroth 2 type, preferably combined with vagotomy. It is not a perfect procedure, but it has proved to be fairly satisfactory in my hands. The incidence of jejunal ulceration appeared lessened by the addition of complementary vagotomy at the cost of a slight increase in postoperative morbidity and in the incidence of a moderate diarrhea.

894 Madison Ave. (21).

Drs. Leonard J. Druckerman and Vernon A. Weinstein performed follow-up examinations of most patients in this series.

MEDICAL EVALUATION OF THE BECK OPERATION FOR CORONARY ARTERY DISEASE

Bernard L. Brofman, M.D., Cleveland

• *The Beck operation, which consists of procedures to effect intercoronary blood-flow communications, has been performed on 185 patients in Cleveland. The operation relieves ischemic areas of the heart muscle, responsible for pain, and can prevent dangerous oxygen differentials that cause death; however, it cannot stop occlusive disease in the coronary arteries, nor restore degenerated myocardium. A positive diagnosis of coronary disease is the indication for operation (unless there is some specific contraindication), and the protection afforded by the operation need not be withheld until the patient has had at least one myocardial infarction. On 137 follow-up studies the long-term mortality has been reduced over one-half from what would be expected, and 90% of those patients still being followed have definite amelioration of previous symptoms. The low operative mortality is attested to by a series of 100 consecutive patients operated on, of which only one died prior to discharge from the hospital.*

The greatest single problem confronting the medical profession today is concerned with the catastrophic consequences of coronary artery disease. The occlusive degenerative process in the coronary arteries results in the incapacity of angina pectoris, the disability of myocardial infarction, and the disaster of the fatal heart attack. By its very nature, this process is progressive and eventually fatal. The annual death toll associated with coronary disease in the United States continues to increase and is fast approaching the half-million mark. This increase is not merely an expression of the general aging of the population; as a matter of fact, coronary disease has become increasingly common in the younger age groups. Many patients with definite coronary disease live out a normal life expectancy with little or no disability, but, unfortunately, the great majority are doomed to prolonged invalidism or sudden death. Despite the increasing devastation of this disease, there has developed a remarkable complacency and feeling of optimism toward the patient with coronary disease. This has progressed to the ridiculous rationalization that patients with coronary disease are better off than those who do not have the disease.

In a fundamental sense, angina pectoris, myocardial infarction, and cardiac arrest merely represent varying responses of the heart to the occlusive process in the coronary arteries. However, there *is no obligate relationship* between the degree of reduction in coronary inflow and the resulting consequences.[1] The essential role of intercoronary arterial channels in preventing the catastrophic consequences of coronary artery disease is evidence of the protection afforded by a more equal distribution of the available coronary inflow.[2] If this collateral circulation is adequate, complete occlusion of the coronary arteries may occur without significant muscle damage. The fate of the myocardium and, indeed, the fate of the patient depends upon the amount of blood available beyond the stenosis or occlusion of the coronary artery. The natural development of intercoronary communications is an uncertain process and is, unfortunately, most frequently inadequate.

Frequent electrocardiograms and the present medical optimism must not disguise the necessity for definitive treatment to provide an adequate distribution of blood to the myocardium. Some day, the occlusive process in the coronary arteries presumably will be reduced or prevented by medical means. However, for the present, the patient with coronary artery disease should have the benefit of any *treatment that is safe and effective.*

Surgical Treatment

The surgical treatment for coronary artery disease has been established on a firm scientific basis.[3] The principles and techniques developed by Beck are generally recognized and have stimulated many workers in this field. In a recent survey, I discovered that more than 50 thoracic surgeons in the United States (and at least 20 in Europe and Israel) have carried out the surgical treatment of coronary artery disease in well over 1,200 patients. The over-all operative and early postoperative mortality reported by these surgeons has ranged between 5 and 10%. Long-term follow-up studies have revealed complete or partial relief from symptoms in 80 to 90% of the patients evaluated. Despite certain variations in the surgical technique, the results have been remarkably similar.

This report is based on observations of 185 consecutive patients operated on in Cleveland by Beck since January, 1951. Briefly, the Beck operation consists of

Read before the Section on General Practice at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

mechanical abrasion of the epicardium and parietal pericardium, partial ligation of the coronary sinus, instillation of powdered asbestos, and the application of mediastinal fat and pericardium to the heart. These procedures are effective in stimulating intercoronary communications and may bring added blood to the heart that has reduced coronary inflow. Effectiveness of the Beck operation has been demonstrated convincingly in the laboratory.[3] Test coronary artery ligation was followed by a much lower mortality rate in dogs that had had the Beck operation than in those not so protected, and resulting infarcts were smaller. Backflow measurements demonstrate increased blood supply beyond the occluded artery.

The clinical results in patients have confirmed the laboratory findings. However, in order to evaluate properly the surgical treatment of coronary disease, it is important to know not only what operation can do but also what it cannot do. It cannot stop the occlusive disease in the coronary arteries, nor can it restore degenerated myocardium. It can relieve ischemic areas responsible for pain; it can prevent dangerous oxygen differentials that cause death[4]; and it can prevent extensive infarction. It should be stressed that pain relief is achieved, not by interruption of pain pathways, but by overcoming the physiological derangement causing the pain. Obviously, interference with normal pain pathways, although possibly producing subjective relief, could not prolong life; on the contrary, such a procedure would result in earlier mortality. It will be shown that the Beck operation definitely increases life expectancy.

In properly selected patients, the mortality associated with operation has been remarkably low. As a matter of fact, in the last 62 consecutive patients operated on up to this time, the operative and early postoperative mortality has been zero. This signal achievement should remove the last imposing barrier to the surgical treatment of coronary artery disease.

Operability

Indications for Operation and Selection of Patients.—The diagnosis of coronary artery disease rests primarily on the patient's history. The electrocardiogram is merely confirmatory. In 25% of the patients in this series, the preoperative 12-lead electrocardiogram was within normal limits at rest. Exercise-tolerance tests, which were performed only in patients with normal control records, showed characteristic electrocardiographic changes of coronary insufficiency in one-half of these. The unreliability of the electrocardiogram was particularly evident in patients in whom serial electrocardiograms had always been normal. In 25% of such patients, exploration of the heart surface during operation, with the aid of exploratory direct epicardial electrograms, revealed previously undiagnosed infarcts.

A positive diagnosis of coronary disease is the indication for operation. The achievement of a low operative mortality rate now justifies the application of the operation to patients with very early disease, that is, before extensive myocardial damage has occurred. By the same token, the protection afforded by operation need not be withheld until the patient has had at least one myocardial infarction; early operation can reduce the 10 to 20% mortality rate associated with the first episode of myocardial infarction. Operation may also be performed even after several episodes of infarction, but, obviously, little benefit can be achieved if the heart has begun to dilate.

Classification of patients with coronary artery disease is particularly difficult. Consideration must be given not only to the degree of myocardial degeneration but also to the progression of the occlusive process in the arteries. The following preoperative classification has been found useful: Group 1 consists of patients, usually under 50 years of age, who have mild symptoms and who may have a small infarct and/or mild angina pectoris. Group 2 consists of patients with hearts of normal size who have moderate to severe angina pectoris; they may have one or more infarcts. Group 3 consists of the salvage cases—those patients with extensive muscle damage who may have an enlarged heart and congestive heart failure—as well as patients with status anginosus and those with certain contraindications for operation. The great majority of patients operated on are in group 2. However, the percentage of patients in group 1 is increasing. As a matter of fact, in members of families with a "bad" coronary history, operation should be considered at the earliest evidence of the disease.

Contraindications for Operation.—Acute myocardial infarction, or even suspicion of impending infarction, precludes operation for at least four to six months. In addition to the obvious dangers of operation during the acute stage, the delay allows for development of natural compensatory mechanisms. Operation is also hazardous in younger patients with rapidly progressive symptoms, particularly in those without previous myocardial infarction. These patients are prone to the development of areas of ischemia during or immediately after operation. Their hearts tend to develop electrical instability,[4] with resultant ventricular fibrillation, so that an impending medical death becomes a surgical mortality.

Cardiac enlargement and evidence of congestive failure constitute a relative contraindication to operation. However, in 20% of the patients operated on in this series, the left ventricle was fluoroscopically enlarged. At least one-fourth of these patients had objective evidence of early congestive failure. Although it is too late for much benefit in such patients, their hearts are remarkably stable and they tolerate operation quite well. Severe hypertension, or any other associated disease that in itself limits life expectancy, contraindicates operation. However, a moderate degree of blood pressure elevation was present in 25% of the patients operated on.

Significance of Age, Sex, and Duration of Symptoms.—In this series of 185 patients who were operated on, the age range was 27 to 72, with an average age of 48 years. Generally, patients over the age of 65 carry an increased operative risk, but operation is not denied such a patient if his tissue age justifies it.

Twenty patients in this series were over 60. In patients under 40 years of age, the rapidly progressive disease usually present in this age group tends to make operation somewhat hazardous. However, operation was carried out in 29 patients under 40 years of age. Less than 10% of the patients operated on were females.

In this series, 75% of the patients had suffered at least one clinically proved myocardial infarction. Two or more infarctions had occurred in 20%. Angina pectoris, ranging in severity from very mild to complete status anginosus, was present in 95% of the patients operated on. The duration of symptoms, in itself, of course gives no indication of the severity of the disease. The range of duration in this series was from four months to 13 years, with an average of 2.9 years. In general, patients with longer periods of duration of symptoms appeared to tolerate operation better.

Results

Mortality.—In the 185 patients operated on since January, 1951, there have been 11 deaths associated with surgery (2 during operation and 9 in the early postoperative period), for a total mortality rate of less than 6%. Careful selection of patients and improvements in medical and surgical management have resulted in a progressive lowering of operative mortality, as evidenced by the last 62 consecutive operations up to this time without a death. At least 15 of the 62 patients were salvage cases. However, in every instance symptoms had become fairly stable for a few months prior to operation. Recognition of the limitations of operation has prompted judicious delay in seriously ill patients. Certainly, if a castastrophe is imminent, an ill-timed operation will only hasten it. A delay of a few months permits time for stabilization and greatly enhances toleration of the operation and the achievement of a good result.

Evaluation.—Obviously, the very nature of the disease itself is such that there is no reliable objective method for the evaluation of any method of medical or surgical treatment for coronary artery disease. Reliance on the electrocardiogram or ballistocardiogram is indeed unrealistic. Furthermore, one must consider the fact that only a small alteration in previously compensated coronary circulation results in disability or death. By the same token, only a small amount of blood made available to a critical area can produce marked clinical benefit. Certainly, in the anginal attack, one would not question the immediate relief afforded by a tiny amount of glyceryl trinitrate merely because such a dramatic accomplishment may not be demonstrable electrocardiographically. Also, the remarkable and immediate response to glyceryl trinitrate further emphasizes the far-reaching effect of small alterations in coronary circulation.

Serial electrocardiograms and ballistocardiograms have been taken in most patients as part of their long-term evaluation. Significantly enough, in 40% of those having abnormal preoperative ballistocardiograms there has been evidence of improvement within the first year; however, there does not appear to be any obligate relationship between the degree of clinical improvement and that shown on the ballistocardiogram.[4a]

Generally speaking, each patient serves as his own control. No doubt, with a few more years of follow-up, a highly significant statistical evaluation will be forthcoming. For the present, evaluation of the effect of operation must rest upon the following factors: (1) increased life expectancy, (2) amelioration of symptoms, and (3) ability to work.

Long-term follow-up studies have been carried out on the 137 consecutive patients discharged over a period of six months to five years, with the average time since operation being two years. The expected mortality in such a group over this period would be 41, or 30%.[7] Actually, 18 are known or assumed to be dead, a mortality rate of 13.1%. Thus, even at this relatively early period, life expectancy can be shown to be increased by operation. Since operation does not prevent the occlusive process in the coronary arteries, a period of symptomatic improvement may be terminated by overwhelming occlusion and death. Such was the case in 50% of the patients who died six months to five years after operation.

Of the 100 consecutive patients who are alive and who could be evaluated over a six-month to five-year follow-up period, 45 are more or less completely free of pain. Another 45 claim considerable reduction in pain. Thus, 90% had a definite amelioration of symptoms. Only 10% had no observable improvement; however, evaluation in these was particularly difficult because of such complications as narcotic addiction, psychoses, and cerebrovascular accidents. Ability to work with no limitations was reported in 42 patients, while another 48 are better able to work, with some limitations. Thus, 90% are economically productive. Prior to the operation only 45% had been able to work half-time or more.

Summary and Conclusions

The Beck operation for coronary artery disease is a safe and effective procedure for providing a more adequate distribution of arterial blood to the heart. In the last 62 consecutive patients operated on, the mortality associated with operation has been zero. The over-all operative mortality since January, 1951, is less than 6%. Operation is indicated in patients with coronary artery disease unless there is a specific contraindication. The operation should not be considered as merely a salvage procedure; best results are achieved by operation early in the course of the disease. Long-term follow-up studies on patients who had undergone the Beck operation revealed a definite increase in life expectancy. Significant amelioration of symptoms occurred in 90% of the patients evaluated. Likewise, 90% of the patients were able to return to full-time or part-time work with less limitation.

Addendum

Since this paper was prepared, the series of consecutive patients operated on without immediate operative mortality has been extended to 100. The only death in this entire series occurred in a poor-risk patient who suffered an overwhelming coronary occlusion just prior to his anticipated discharge from the hospital.

SPECIAL INDICATIONS FOR HYPNOSIS AS A METHOD OF ANESTHESIA

Harold B. Crasilneck, Ph.D., E. James McCranie, M.D.
and
M. T. Jenkins, M.D., Dallas, Texas

• *The advantages of hypnosis as an alternative to conventional anesthesia in special instances are illustrated by accounts of five cases. In a pregnant woman about six weeks before term, the onset of poliomyelitis caused paralyses so extensive as to require tracheostomy and continuous respiratory assistance; when it was decided that labor should be induced, hypnosis was tried and found adequate for the delivery of a 2,664.9-gm. infant by low forceps. In a dental patient who had been insisting on general anesthesia after severe reactions to a local anesthetic, hypnosis solved the immediate problem and eventually diminished the patient's fear of dentistry. In a severe case of epilepsy, hypnosis sufficed for the craniotomy and excision of the epileptogenic focus in the temporal lobe after procaine was injected for the scalp incision. Hypnosis was found adequate similarly in a man who needed extensive débridement and grafting after thermal burns covering 45% of his body surface and in a girl who needed gynecologic surgery in the presence of severe congenital heart disease. The disadvantages of hypnosis, that it requires skill, is time-consuming, carries psychological risks, and fails in some subjects, are offset by its advantages in special cases. Its indiscriminate use .in uncomplicated cases is not recommended.*

The beginnings of the use of hypnosis as an analgesic agent go back to ancient times. One of the first recorded reports of its use in surgery in modern times is that of Esdaile, published in 1840. Since then there has been extensive documentation of its efficiency as an anesthetic agent. In spite of this, hypnosis has not yet gained widespread use as an anesthetic agent. This is due partly to the inherent difficulties in the hypnotic technique and to the quasi-scientific status that is usually associated with hypnotism in the mind of the scientific man. More important, however, than either of these is the rapid development of modern anesthesiology with its more efficient and safe techniques and chemical agents. Because of this, it hardly seems practical to advocate the general use of hypnosis as an anesthetic agent. It frequently happens, however, that special kinds of problems or procedures arise with patients in whom the administration of chemical anesthetics might be undesirable. For the past three years we have been investigating the use of hypnosis as a method of anesthesia in such special kinds of surgical problems. The purpose of this report is to present some of these problems and the results obtained through the use of hypnosis.

Report of Cases

Case 1.—A 32-year-old pregnant woman developed poliomyelitis about six weeks before term. Previously she had experienced three normal pregnancies and deliveries, and her fourth pregnancy had been completely normal prior to the onset of the poliomyelitis. Twenty-four hours after the patient's admission to the hospital, extensive paralysis occurred. Involvement of muscles of respiration limited her tidal volume to 200 ml. of air, as determined by pneumotachographic studies. Her vital capacity at this time was not significantly greater than her tidal volume, and control of pharyngeal secretions was accomplished with difficulty. A tracheotomy was performed, and her breathing was assisted by the use of an intermittent positive-pressure type of respirator. She needed continuous respiratory assistance, and it was elected to continue use of intermittent positive-pressure and nebulization with the patient in a comfortable low Fowler position.

Both the obstetrician and the respiratory consultant felt that emptying the uterus would improve the patient's general condition. Two days after the patient's admission, the obstetrician started an intravenous infusion of oxytocin injection (Pitocin) and isotonic sodium chloride solution. Excellent uterine contractions were maintained for about six hours, although dilatation of the cervix did not occur. Because the patient had become very tired and apprehensive, it was decided to delay further efforts at induction.

On the fourth day, the internist felt that delivery was more urgently indicated than ever in order to facilitate respiratory exchange. Consequently, another oxytocin infusion was started. This resulted in excellent uterine contractions. The membranes were ruptured, and labor progressed in a satisfactory way. During this prolonged period of labor, the patient had become increasingly anxious and apprehensive. Original plans to utilize a pudendal block to provide anesthesia for delivery were changed. Although use of an inhalation technique of anesthesia was not fundamentally ruled out, hypnosis was given consideration and one of us (H. B. C.) was consulted by the obstetrician concerning this method of anesthesia. The idea of using hypnosis was presented to the patient. Although she at first appeared resistant toward the method, rapport was soon established. She was able to enter a somnambulistic state in spite of the fact

---

From the Southwestern Medical School, University of Texas.

that labor contractions were already occurring every three minutes. She was given the suggestion that her pain would completely cease and that she would become relaxed, unafraid, and cooperative. The suggestions were effective almost immediately. She appeared relaxed and did not show evidence of pain, tension, or apprehension.

She was delivered of a 2,664.9-gm. (5-lb. 14-oz.) male by low forceps without premedication or any anesthesia other than hypnosis. She made no complaint of pain throughout the delivery. The muscles of the perineum were relaxed, and no laceration was sustained. Assisted respiration was continued during the delivery. Following delivery the patient was awakened after being given the posthypnotic suggestion that she would be relaxed and comfortable. The mother has made slow but continuous progress, although paralysis of muscles and weakness persist.

Case 2.—A 36-year-old female was sensitive to procaine. Because of this she objected to the use of any local anesthetic agent. For the previous three years she had refused to allow her dentist to perform even minor procedures without administration of a general anesthetic. Injection of procaine, according to her physician, resulted in severe reactions characterized primarily by edema of the face and body, urticaria, and nausea and vomiting. Since it was impractical to administer an anesthetic each time she required dental procedures, the patient soon refused to return to her dentist. Most of her teeth eventually developed caries. Because of the complexity of the total situation, we were asked to evaluate the patient as a suitable subject for the use of hypnosis as an anesthetic. Personality evaluation indicated an individual relatively free of emotional symptoms other than extreme fear of dental procedures. After a discussion of hypnosis, she proved to be an excellent subject and was soon capable of entering a state of somnambulism. Thereafter, on five separate occasions dental procedures lasting approximately two hours each were successfully performed with the patient under hypnosis. During these procedures she was free of all pain and of apprehensiveness. Eventually her fears of dental procedures were greatly diminished, and now she is capable of undergoing at least minor procedures without hypnosis.

Case 3.—A 14-year-old girl had developed epileptic convulsions after a head injury four and one-half years prior to her admission to the hospital. The convulsions occurred at the rate of two or three per day and were usually preceded by an aura consisting of a "tingling sensation in the fingers of both hands" and accompanied by a loss of consciousness of from 30 to 60 seconds. Electroencephalographic studies revealed a focal discharge in the right temporal lobe. Anticonvulsive medication was successful only to the extent of reducing the number of daily seizures.

Since conservative treatment was not considered adequate and since there was a temporal focus, it was decided to perform a temporal lobectomy with electroencephalographic monitoring. It became necessary to consider the effects of anesthetic agents given by inhalation or intravenously upon the electroencephalographic patterns. Since it is well established that there are no alterations in the brain wave patterns in even the deepest state of hypnosis,[1] it was decided to try hypnosis plus local infiltration of the scalp with procaine for the anesthesia. The possibility of using hypnosis was discussed with the patient. She proved to be an excellent hypnotic subject and was hypnotized four times before surgery to condition her to enter the somnambulistic state required for the proposed surgery.

At operation the scalp line of incision was injected with a 2% solution of procaine. She was then hypnotized and, after she had entered a state of somnambulism, the surgical procedure was started. During most of the operation the patient was relaxed and comfortable. She did, however, complain of a mild pain while the dura was being separated from the bone. Twice during the nine-hour procedure it was necessary to inject the scalp with additional local anesthetic because of the patient's perception of pain, especially upon forceful retraction of the scalp margin. The abnormal spiking electrical focus was confirmed by electroencephalographic tracings, and the proposed excision of the focus was performed. The patient did not complain of pain during this excision except on one noteworthy occasion when, as a blood vessel in the hippocampal region was being coagulated, the patient suddenly awoke from the hypnotic trance. She was immediately rehypnotized and was able again to enter a deep state of somnambulism. (The fact that the patient woke from the hypnotic state when the hippocampus was stimulated has led to considerable interest and speculation on our part as to the neurophysiology of hypnosis, and it opens another avenue for investigation.) The final electroencephalographic tracings revealed no further abnormalities. After electroencephalograms were completed, the patient was given 100 mg. of thiopental sodium intravenously. She remained in excellent condition throughout the procedure. Upon completion of the operation, she was able to answer questions but was amnesic concerning the surgery because of a posthypnotic suggestion given prior to awakening. She had also been given a posthypnotic suggestion that she would experience a prolonged sleep, which she did for six hours without further sedation. The postoperative course was very satisfactory and free of complications.

Case 4.—A 33-year-old male had thermal burns covering 45% of the body surface. During the first phase of treatment he required numerous changes of dressing and débridements. It soon became necessary to administer a general anesthetic for these changes because of pain elicited in manipulating his extremities during the procedure. He became progressively fearful of the frequent anesthesia and was generally withdrawn, negativistic, and uncooperative. Therefore, it was decided to use hypnosis as an analgesic during these changes of dressing and débridements. The patient was a good hypnotic subject, and the hypnotic procedure was successful both as an analgesic and in improving the patient's general mental state. Hypnotic sleep was used as the anesthetic agent during the next surgery. Extensive débridement was carried out and a split-thickness skin graft was taken from the right leg. He was given the posthypnotic suggestion that he would perceive no pain in the donor area or in the area of débridement. Upon his awakening, the suggestion was in effect. Two days later the sensations of pain and touch were restored by hypnotic suggestion. The patient's recovery was rapid and without complications.

Case 5.—A 34-year-old single female with severe congenital heart disease had repeated x-ray examinations over a period of years that revealed an extension of the pulmonary artery shadows with congenital changes consistent with a diagnosis of Eisenmenger's complex. Approximately six months prior to the time of referral, the patient began having extreme difficulty in her menses. Menstrual flow lasted from 15 to 17 days. At the onset of such a period, bleeding was described as excessive and heavy, resulting in spotting during the last few days. A pelvic examination revealed the patient to be a nulligravida with a virginal introitus. Because the hymenal ring was so tight and because the patient was extremely anxious and tense, her gynecologist was unable to perform an adequate pelvic examination. The gynecologist was of the opinion that dilation of the cervix and curettage of the uterus were indicated for purposes of diagnosis. However, both the gynecologist and cardiologist felt that the patient presented a definite anesthetic risk. Although it was agreed that a caudal or a saddle block would be acceptable, it was also agreed that hypnosis might be safer if the patient were a suitable subject.

Personality evaluation revealed that the patient was very immature emotionally and highly dependent on her mother. Her social activities were limited and were always approved by the mother beforehand. She seldom dated and was extremely naïve and fearful of any kind of sexual activity, preferring not to be alone in the company of men. Because of her emotional immaturity and numerous neurotic conflicts, it was feared that the extensive use of hypnosis might arouse more overt symptoms of psychiatric illness. However, it was decided that this risk was worth taking because of her physical status. After reasonable rapport had been established with the patient and the possible use of hypnosis had been explained to her, she accepted the proposal, although she was obviously anxious about how she would respond to this method and whether she would be a good subject.

Actually she turned out to be a good subject and was hypnotized three times prior to surgery to condition her to enter a state of somnambulism. A pelvic examination was done by the gynecologist during the third session. It was suggested to the patient that she would be free of pain and completely relaxed during the examination. While the patient was in a state of hypnosis, the gynecologist reported that it was possible to do a very adequate bimanual examination. There was neither subjective nor objective evidence of pain, tension, or anxiety during this procedure.

The patient was operated on a week later. No medicaments were administered preoperatively. After she was hypnotized, cervical dilation was accomplished, and endometrial curettage was then performed. The patient slept throughout the entire operative procedure and evidenced no perception of pain. She was given a posthypnotic suggestion that there would be no cramping or undue discomfort. After her return to the recovery room, the posthypnotic suggestions were in effect, with no pain, cramping, or discomfort reported by the patient. At the end of the hour, it was then suggested that normal bodily sensations would return to her. She was awakened from the hypnotic sleep and was amnesic for the entire procedure. Her pulse, blood pressure, and respiration showed no significant deviations prior to, during, or after the surgery. Her recovery was uneventful and free of complications.

Comment

The five cases presented represent instances in which hypnosis was considered to have special advantages over conventional anesthetic methods. As a result of our experience with these cases, some special indications for hypnoanesthesia can be formulated. First, it is indicated in cases in which chemical analgesics and depressants are contraindicated or dangerous because of respiratory or cardiac disease. This type of indication is illustrated by cases 1 and 5. Second, it is indicated in cases in which the preferred anesthetic agent cannot be used because the patient has demonstrated sensitivity to it. This is represented by case 2. Third, hypnoanesthesia should be used in cases in which the repeated use of anesthetics tends to have a debilitating effect on the patient with an already disturbed physiology. This is frequently a problem with severely burned patients who require frequent painful changes of dressings, débridement, and skin grafts. This type is illustrated by case 4 and has been more extensively elaborated on in a previous paper[2] reporting cases in which hypnosis was used to augment ambulation and other exercises as well as to increase food intake in burned patients.

Fourth, it is indicated in patients whose apprehension and fear of general anesthesia are so great as to interfere with its smooth application or even to result in serious anesthetic risks. This type is illustrated by cases 1 and 4. Fifth, hypnosis should be utilized in patients whom it is desirable to free of some of the neurophysiological effects of the anesthetic. This is illustrated by case 3. In such a case, it was desired to avoid the effect of drugs on the electroencephalogram. In other types of neurosurgical operations, it might be advantageous to have the conscious cooperation of the patient during the operative procedure, in which case hypnosis would be an ideal type of anesthesia. Another advantage in neurosurgical cases is associated with the length of time of the operation. Hypnosis obviates the debilitating effects of prolonged chemical anesthesia.

There are definite disadvantages in the use of hypnosis as a method of anesthesia. There are, for example, many individuals who cannot be hypnotized. Furthermore, some persons who are hypnotized are not capable of entering the depth of hypnotic state necessary to produce sleep and lasting anesthetic effects. It may be originally time-consuming. It also requires special training and skill on the part of the hypnotist. There are also risks involved in hypnotizing patients who have psychological problems. A careful psychiatric evaluation should be performed prior to the use of hypnosis.

Summary and Conclusions

In a series of five cases, hypnosis was used as preferable to chemical anesthesia. The use of hypnoanesthesia should be reserved for cases with special indications, because there are definite psychological hazards to its indiscriminate use and in most uncomplicated cases its use is neither practical nor economically feasible.

The Filter Organs.—The spleen, lymph nodes, and probably all lymphatic tissue possess unique phagocytic, cytopoietic and antibody-forming capacities which are functional in immunity. . . . The immunological functions of the spleen are chiefly directed toward invading organisms and other antigens which occur in the blood because its macrophages are oriented to remove materials from the blood. The spleen, therefore, should be compared with other filter organs of the blood, i. e., the liver, bone marrow, adrenal and pituitary. Of these, the liver, probably because of its size, is of greatest importance phagocytically, but, although it synthesizes serum globulins, is probably unimportant in antibody formation . . . except after lymphatic tissue appears in the periportal connective tissue as frequently happens during intense immunization or infection. . . . The bone marrow forms antibody, but how much is not known. Although relatively insignificant phagocytically, it supplies most of the heterophils which act as a first line mobile defense in certain infections. The heterophil, however, even in pyogenic infections, is probably less important than the macrophage. . . . The adrenal and pituitary are erratic as phagocytic centers and are not important sites of the cytopoiesis of connective tissue cells involved in immunity. To them have been ascribed various functions in the destruction of lymphoid cells and the release of antibody, but the extent and true significance of the pituitary-adrenal-cortical hormones in immunity still needs clarification. . . . Thus, it is evident that the spleen is not unique among the filter organs in any single function concerned in immunity, but is unique in the heterogeneity of its functions. I shall consider in order its phagocytic function, its cytopoietic activity including the production of lymphoid cells and macrophages, its role in the formation of specific antibodies and certain little understood regulatory actions on nonsplenic antibody-forming sites.—W. H. Taliaferro, M.D., Functions of the Spleen in Immunity: Presidential Address, *The American Journal of Tropical Medicine and Hygiene*, May, 1956.

CLINICAL NOTES

A MODIFIED SPINE BRACE

Robert C. Cornell, M.D., Bangor, Maine

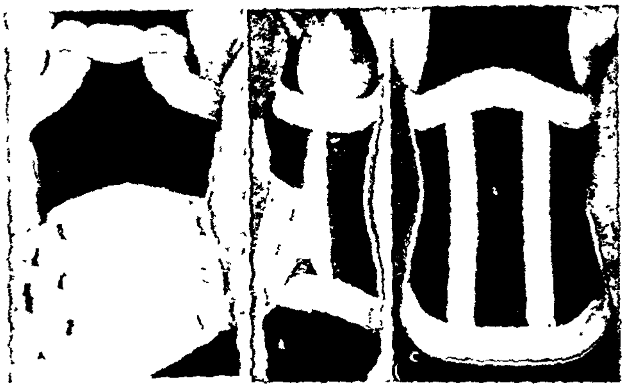
The medical literature of the past two decades is well endowed with descriptions of various types of spine braces. The majority of these are quite adequate and are as comfortable as an appliance of this type is expected to be. The brace to be described is the result of modifications of previously described braces; thus I claim little originality. In 1937, Arnold[1] described an efficient back brace. Using Arnold's brace as a pattern, I have made a number of modifications designed to increase the range of usefulness of the appliance and to increase patient comfort. In 1942, Baker[2] described a brace that he used on patients with arthritis of the spine, and Williams[3] described a brace for use in flexion management of low back conditions. Some of the ideas embodied in these two braces have been incorporated in the apparatus herein described.

Uses

As do most orthopedic appliances, this brace has its limitations, and it is not intended for the treatment of all conditions involving the spine. It is designed primarily for immobilization or stabilization of the spine from the sacrum to the seventh thoracic vertebra and is not intended for the support of the cervical and first seven thoracic vertebrae. Lumbosacral fusions can be adequately supported by shorter braces, and consequently this apparatus is not intended for that purpose. I have used this brace for the treatment of fractures of the thoracic spine distal to the seventh thoracic vertebra, thoracic kyphosis caused by juvenile epiphysitis, rheumatoid spondylitis, and incorrect posture. It has been an excellent brace for the treatment of fractures of the thoracic and upper part of the lumbar spine and has been successfully used postoperatively for fusions of the thoracic and lumbar spines. It has been used to support the spine during recovery of patients from poliomyelitis and is particularly useful in those instances in which the respiratory musculature is involved, as in bulbar poliomyelitis.

Advantages

This brace has a number of distinct advantages from the point of view of patient comfort. The apparatus is constructed from measurements taken on a flexible jig, and all components are built to conform to the contours of the patient's body. Accurate measurements can be taken in the hospital or in the doctor's office, and rarely are more than minor adjustments necessary after the brace has been completed. The brace is lightweight, easily adjusted, and may be put on in the operating room and adjusted to meet individual requirements at any given moment (see figure, A). The axillary portion of the brace does not extend high enough into the axillas to be uncomfortable and allows freedom of movement of the upper extremities (see figure, B). The lower or pelvic band is form-fitted and grips the pelvis in such a manner that the brace does not ride up or down when the patient moves. The posterior longitudinal bars (see figure, C) are placed 4 in. apart, 2 in. on either side of the spinous processes, to allow for a surgical dressing in the event that the brace is being used after a spinal fusion. Furthermore, placing the longitudinal bars in this way decreases pressure over the spine itself and adds considerably to the patient's comfort. The lack of constricting bands about the lower part of the chest makes the brace a useful appliance both in injuries in which there has been damage to the chest wall and in conditions in which there is concomitant respiratory embarrassment without injury to the patient. For instance, the brace has been used on a 6-year-old boy recovering from bulbar poliomyelitis; it supported the spine and shoulders without respiratory interference. The absence of over-the-shoulder straps makes this brace useful in instances in which there is an injury to the shoulders with concomitant injuries to the spine.



Modified spine brace. *A*, anterior view. Chest pieces can be made lower and transverse strap can be removed. *B*, lateral view. *C*, posterior view. Note space between upright bars.

Description

The brace is a singularly uncomplicated appliance. It consists of a pelvic band molded to the contours of the sacrum and ending immediately beneath the anterior superior iliac spine. Thus, the pelvic band fits well, does not slide around when the patient moves, and becomes a well-stabilized point of fixation for the lower portion of the brace. The upper circumferential band fits snugly against the upper portion of the back and varies considerably in its contours depending upon the degree of immobilization required. It extends anteriorly beneath the axillas on each side and then curves upward to end in a wide flare that conforms to the anterior chest wall in the pectoral region.

There are four longitudinal or upright bars; two are placed posteriorly 4 in. apart and the remaining two lie in the midaxillary line, one on each side. A light leather strap connects the two anterior chest pieces to prevent separation.

The circumferential bands and longitudinal bars are constructed of no. 24 S. T. Dural. The pelvic band is 1¾ in. wide and made of 18-gauge material. The upper circumferential band is 1¼ in. wide and made of 24-gauge Dural, which allows sufficient springing of the brace to facilitate its being put on and off. The upright bars are made of 24-gauge Dural that is ½ in. wide. All metal parts are padded with horse hair and felt, and then covered with elk hide. The lower portion of the brace is held in place by a wide abdominal apron with four adjustable straps. The metal portion of the brace is riveted together with rivets of stainless steel, a deterrent to rust and corrosion. The portion of the thoracic band that passes beneath the axillas is heavily padded with sponge rubber and covered with elk hide.

Summary

A simple but useful spine brace has been developed that has a wide range of usefulness and is more comfortable to the patient than previously described braces.

COUNCIL ON MENTAL HEALTH

The following article is the first of a series of planned articles, which will include discussion of the medical treatment, the physiological aspects, the psychiatric aspects, and the sociologic aspects of alcoholism. After publication of the series, it is planned that the articles will be combined, along with other material, into a pamphlet on the up-to-date treatment of alcoholism as an illness, for the use of medical practitioners generally. It is the belief of the Council and the members of its Committee on Alcoholism that much of the recently developed information on the most effective methods of treating the problems of alcoholism in private practice and in hospital management has not had wide circulation and that, as a result of this, many of the patients with this illness are not now receiving the necessary attention and treatment that could and should be given them. In view of American medicine's recognition of alcoholism as a disease and not as a problem of morals, as related in the recently published statement on "Hospitalization of Patients with Alcoholism," which appears in the "Reports of Officers" in The Journal, *Oct. 20, 1956, page 750, the Council and its Committee members believe that an intensive effort is now necessary to provide these patients with the proper medical care and consideration they so urgently need.*

The next two articles in the series, as now planned, will be on the physiology of alcoholism and on the psychiatric treatment of alcoholism.

MEDICAL TREATMENT OF ALCOHOLISM

Marvin A. Block, M.D., Buffalo

The medical treatment of alcoholism is rapidly becoming more important in accomplishing recovery for patients with this disease. Because of the fear and threat that so many alcoholics feel about any treatment, a medical approach seems much more acceptable. With the general feeling of physical well-being, any type of therapy becomes less of a threat and the cooperation of the patient becomes much more possible.

It is important, therefore, that the patient be given as healthy a physiological basis as is possible before any type of therapy is applied. With the newer medications at the disposal of the therapist, a medical approach can be used with much better results and fewer untoward side-effects than with the older types of medications. The medical treatment also offers an avenue for many more practitioners to treat alcoholics than heretofore, because the newer drugs allow for a greater feeling of comfort for the patient, without the lethargy that former types of therapy had produced. He is then also more receptive to other types of therapy.

The practicing physician should be equipped with knowledge of the medical treatment of this illness when he encounters such a patient. Once this treatment has produced the desired effects, other types of therapy may be employed as indicated. The following outline of treatment is intended as a general medical approach to the problem and is arranged in such order as to fit within the framework of the practicing physician's experience and knowledge of medicine, physiology, pharmacology, and psychiatry. Special cases and complications may require the aid of experts in various specialties, but, for the vast majority of such patients, this outline will serve.

Chairman, Committee on Alcoholism.

Acute Alcoholic Intoxication

The acute state of alcoholic intoxication may occur in any individual, be he an alcoholic or not. It represents a period of excessive drinking that renders the individual unable to function effectively. The intoxication may vary in the degree of intensity as well as in duration. Reactions to intoxication by alcohol have a wide range, depending upon the individual involved. There is a general characteristic behavior of acute alcoholic intoxication, but, since it varies with the reactions of the individual and depends largely upon the emotional response to withdrawal of his control, all do not react exactly alike. Without his controls, the individual will respond to various stimuli affecting his interpersonal relationships with his family, friends, employers, and fellow employees. Such relationships without control of emotions and judgment may result in severe tragedies and unpleasant consequences. When such actions are contrary to law, they may result in consequences having far-reaching effects. When they are contrary to good judgment, as in the case of automobile accidents, physical harm and even death may result.

The objective of the physician with a patient in this state of acute alcoholic intoxication is to detoxify him as quickly as possible, so that the effect of the alcohol no longer obtains. It is useless to attempt further remedial measures, such as psychotherapy, while the patient is in the acutely intoxicated stage, since there is no judgment present for him to use, nor is there sufficient understanding to make an impression when he is befuddled. This does not mean, however, that recovery during the alcoholic acute stage should not be utilized for the purpose of indoctrination. It is much more sensible, however, to wait until the patient's mind has cleared and he can understand and cooperate with the therapist.

It does not necessarily follow that psychotherapy must only be administered if the patient requests it. Such therapy can be administered without the patient being aware of it. Many such patients in emerging from their alcoholic stupor express an intense desire to be returned to the somnolent state. To accede to these wishes would only prolong the period of intoxication, whether that intoxication then be from the alcohol or from sedative drugs administered by the therapist. There are times when the patient is acutely active, when it is necessary to administer drugs as substitutes for the alcohol, but these drugs must be given judiciously and not necessarily at the patient's request. It must be remembered that alcohol acts as an anesthetic agent, with the same effect as any other anesthetic, and the same stages of anesthesia are experienced. Both during induction and when the patient emerges from the anesthetic, he goes through an active phase. With other agents such as nitrous oxide or ether, the stage is much shorter than with alcohol. Since the stage of activity with alcohol is longer than with the other anesthetic agents, it is necessary at times to use sedation to keep such activity from getting out of control. This stage of activity, when the patient is emerging from the acute intoxication of alcohol anesthesia, must often be controlled by giving sedatives.

Hospitalization

While it is not always necessary to treat the patient with acute alcoholic intoxication in a hospital, there is no doubt that this is the best setting for such treatment. It is of advantage to both the physician and the patient to have the hospital accept these patients. It is in the hospital that the laboratory procedures so often necessary can be carried out quickly and thoroughly. Intravenous therapy is readily available. Emergency measures are at hand. There is no substitute for the general hospital in caring for these patients, and anyone with experience in treating alcoholics will agree that there is very little difficulty with most of them, contrary to the general impression of some personnel. Records of hospitals that have admitted these patients will confirm the report that most of these patients offer no more difficulty than any other sick person. On the contrary, the attitude of the hospital toward the acutely ill alcoholic patient that he is sick and welcome for treatment makes these patients more cooperative than many other hospital patients. There are exceptions to this rule, of course. Patients in delirium or unusually active patients may cause some difficulties. However, with the newer methods of treatment, these phases can be passed through so rapidly that they represent no great problem to the hospital or to the physician. Even with these patients, no more help is required than with the patient recovering from an anesthetic after surgery.

There are other advantages in having the alcoholic patient in a hospital during the acute phase. All too frequently, the family of the alcoholic is in an unfavorable emotional state during the patient's intoxication. They do not know how to cope with the situation or how to react to the alcoholic's strange behavior. Some, with the best of intentions, continue to give alcohol to the alcoholic. Others, in an attempt to stop his drinking, get into difficulties with the patient suffering emotional reactions resulting from abstinence. In other instances the living conditions and environment of the alcoholic may be the specific cause for his going on his binge, and in this environment he continues to be irritated and continues his drinking. Removing him from such irritating surroundings is at least one way of helping him refrain from drinking. His presence in the hospital enables the physician to carry on with the laboratory procedures, to change medications without difficulty, to try many approaches, and in other ways to control the situation more accurately. From the point of view of the hospital, especially the teaching hospital, it gives the house staff and the nurses an opportunity to deal with these patients and to learn the various ways in which they may react. It prepares the members of the resident staff for the care of this type of patient after they leave their hospital training. None of this must imply that hospitalization is an absolute necessity for most of these patients. With the proper environment in the home, with the proper people to care for the patient, and with the necessary medication, the same type of therapy can be carried on elsewhere. Some nursing homes are well equipped for this, but for the most part they are not the ideal place to care for the acutely ill alcoholic patient.

Evaluation of the Patient's Condition

As with any other sick person, the first step in therapy is a complete physical examination and evaluation of the patient's condition. The smell of alcohol on the breath does not necessarily mean that the apparently intoxicated individual is, in reality, in a state of acute alcoholic intoxication. Other types of poison, head injuries, or other concomitant constitutional diseases may render the patient unconscious, and this type of illness must be ruled out before the patient can be said to have acute alcoholic intoxication. The smell of alcohol on the breath is not necessarily conclusive. It is here that laboratory procedures and x-rays can be of great value. Hemiplegia, diabetes, insulin shock, concussion, and many other such illnesses might give the appearance of acute alcoholic intoxication if the patient with such a condition has been drinking. In reality there may be but little alcohol present, even though the breath carries the smell, and the unconsciousness may be due to another serious physical condition. Complete physical and laboratory procedures will determine the presence or absence of such concomitant conditions. Blood concentration tests for alcohol can be very valuable, where there is grave doubt, but will only determine the depth of the alcoholic intoxication. They will not necessarily rule out any additional physical factor.

In most cases of prolonged drinking, dehydration exists. This can be corrected by reestablishing fluid balance. The addition of saline solution and dextrose or fructose will help meet this emergency. Where deficiencies of diet have existed over periods of time, this condition also must be corrected. Nutritional elements and fluids taken orally preclude the necessity for further measures in this respect. However, when there is considerable vomiting, the dehydration is usually acute and there is a lack of nutritional as well as mineral elements. Such defections can be corrected by intravenous therapy, which is easily administered. A saline solution containing 5% of dextrose may be administered in 1,000-to-2,000-cc. doses in the course of 12 to 24 hours. This can be repeated every day for three days, if necessary. The addition of an ampul of vitamin B complex and ascorbic acid insures an adequate supply of these supplements and will provide the necessary balance of mineral and vitamin content.

Among other agents used in cases of acute intoxication, many therapists believe that insulin accelerates the metabolism of alcohol in the body. To accomplish this, 20 to 45 units of regular insulin may be added to the saline solution for intravenous administration. Before administration, however, it is wise to obtain a determination of a blood sugar level to make sure that the insulin is not given during a hypoglycemic state. Medicaments employed in acute alcohol intoxication are best classified by the response of the presenting symptoms to their administration.

Drugs That Stimulate the Central Nervous System and Counteract Depression

When the patient is extremely drowsy and somnolent or severely depressed as a result of excessive ingestion of alcohol, such effects can be counteracted by the administration of caffeine and sodium benzoate, dextro amphetamine (Dexedrine), or amphetamine (Benzedrine). Another drug that has the same effect and that will counteract such depression and stimulate the central nervous system is methylphenidate (Ritalin) hydrochloride. This medicament, given in dosage of 10 mg., has been found advantageous in counteracting severe depression and somnolence. Still another drug used for the same purpose is pipradrol (Meratran) hydrochloride [alpha-(2-piperidyl) benzhydrol hydrochloride]. The dosage of this drug is 2 to 25 mg. daily, depending upon the severity of the narcolepsy or depression.[1] In severe hypotension, ephedrine may be administered subcutaneously, intramuscularly, or intravenously. For patients in the very severely depressed stage, some therapists have advocated the use of pentylenetetrazol (Metrazol), 1 cc. given directly into the vein. This should be used with caution, as large doses may cause convulsions. These analeptic agents are of value only when the patient is so depressed that he cannot be aroused or if the pulse is markedly reduced in rate or quality. In most cases where there is mild stupor present, if the pulse and respiration are within normal limits, the patient will usually rouse from his stupor after the alcohol is metabolized, without the necessity for using additional drugs.

Drugs That Depress the Central Nervous System

In treating presenting symptoms such as excitability, restlessness, nausea, vomiting, and hyperactivity, measures are sometimes necessary that will control the patient and enable treatment to continue. Although to some extent in the past the use of adrenal cortex extract and the steroids has simplified the control of the acutely ill and hyperactive alcoholic, the recent advent of the tranquilizing drugs has been of tremendous value in treatment of this stage of the illness.

Tranquilizing Drugs.—The use of these tranquilizing drugs has all but revolutionized the treatment of the acute alcoholic stage. Such drugs as reserpine, chlorpromazine, meprobamate, and promazine hydrochloride have proved of immense value in treating the acutely intoxicated patient. The patient not only is given a sense of comfort that enables him to sleep but is also relieved of his nausea and is able to eat much earlier than heretofore. Chlorpromazine is comparatively rapid in its action and can be given intravenously, intramuscularly, or orally in doses ranging from 25 to 100 mg. every four hours.[2] Dosage will depend upon the patient's reaction to the drug. Larger doses are required with some patients than with others. The potentiating characteristics of chlorpromazine must be borne in mind, since the drug increases the sedative effect of the alcohol itself as well as any other sedative drugs that may be given. In most cases, however, no further sedation is required other than administration of chlorpromazine.

Reserpine, which acts more slowly than chlorpromazine, is usually given in doses of 0.25 mg. to as high as 1 mg. every four hours.[3] Although its action is slower than that of chlorpromazine, the effect of the drug apparently lasts longer. It is well to watch the hypotensive action of this drug when it is administered, although, in patients with normal blood pressure levels, it rarely has such an effect. Chlorpromazine, on the other hand, particularly when injected intramuscularly, will often give a rather severe hypotensive effect within the first 30 minutes. This possible effect must be watched closely and the patient placed in a supine position to overcome such effect. Reserpine is the refined alkaloid of Rauwolfia serpentina, but the crude drug is also very effective in the treatment of alcoholics. It acts more slowly than reserpine, but its action may last longer. Its tranquilizing effect takes longer to produce, but the patient can be kept on a regimen of smaller doses over longer periods of time.

Meprobamate (2 methyl-2-n-propyl-1, 3 propanediol dicarbamate), commercially known as Miltown or Equanil, has also been used effectively as a tranquilizer for alcoholics.[4] It also has a decidedly tranquilizing effect upon the patient, reducing the tension and allaying some of the anxieties so common in the alcoholic. It is related to mephenesin (Tolserol), formerly used by many for the treatment of alcoholism. This will be discussed later. Doses of meprobamate vary from 500 mg. given once or twice daily to the same amount given four times a day. For maintenance therapy, dosages are usually smaller. Once the condition is stabilized, it can be maintained indefinitely on therapy with a smaller amount of this drug.

An additional tranquilizing drug, promazine hydrochloride, commercially known as Sparine,[5] is also very valuable in the treatment of alcoholism. It is given in doses varying from 25 to 200 mg. three or four times a day, depending upon the reaction of the patient to this drug. It can be given intravenously, intramuscularly, or orally and has been found to be valuable in the more acutely disturbed patient, bringing about quick sedation and tranquil sleep. The patients awaken refreshed and with a good appetite.

All of the tranquilizing drugs have some beneficial effect. They produce relaxation without sleep. Their value lies in reducing tension and in allowing the patient to remain aware of his surroundings and available for psychotherapy. There have been some reports made of habituation to these drugs. However, such danger can be minimized by changing the drug at frequent intervals. There are some patients, however, who apparently become habituated to anything prescribed. Even placebos seem to offer such opportunities for these patients.

One must always look for the side-effects of these tranquilizing drugs. Chlorpromazine has been known to cause severe jaundice, and, in many cases, severe dermatitis of the allergic type. This can be counteracted by the administration of an adequate antihistaminic such as diphenhydramine (Benadryl) hydrochloride, 50 mg. three times a day. The two drugs can be given concomitantly to avoid this possibility. The latter antihistaminic is in itself somewhat hypnotic and sedative in action. The combination, therefore, with the chlorpromazine produces adequate rest as well as tranquilization. The most common side-effect of the administration of Rauwolfia serpentina or reserpine is a congestion of the nasal passages and mucous membranes. This also can be counteracted by the administration of an antihistaminic. So far there have been no great untoward reactions reported on the use of meprobamate or promazine hydrochloride. With promazine hydrochloride, one case of agranulocytosis has been reported but, on the basis of investigation, might be considered questionable.[6] Although for the most part barbiturates are not recommended for the treatment of the alcoholic, mephobarbital (Mebaral) has been recommended by some as an efficient sedative.

Many physicians treating alcoholics use these tranquilizing drugs to the exclusion of all other sedation and have obtained good results with this type of therapy. Even with patients in delirium tremens and extreme hyperactivity, these drugs have been used very effectively, although larger doses may be necessary.

Adrenal Cortex Extract.—For a long time, the use of the aqueous solution of adrenal cortex extract was popular.[7] This was administered on the theory that the glucose metabolism of the body was altered in the alcoholic and that depleted glycogen stores could be restored to normal by administration of adrenal cortex extract. It was believed by most that the adrenal cortex exhaustion in alcoholics results from continued emotional disturbances and produces upsets in the glucose metabolism. The adrenal cortex extract solution is still used intravenously by many and has been found of great help. The dosage varies from 10 to 30 cc. in 1,000 cc. of saline solution injected over a period of several hours. Where the adrenals seem to be exhausted to a greater extent and the reaction is more severe, from 10 to 20 cc. of the aqueous solution may be administered directly into the vein. It has been found to produce a very quieting effect on the patient, to reduce his anxiety, and to induce a tranquil sleep. Where the patient is extremely tremulous, from 10 to 50 cc. of mephenesin aqueous solution may be added. Although the relief from the tremors in these cases is temporary, it does help the agitated patient.

Paraldehyde.—Another drug that has enjoyed great popularity for many years among many practitioners is paraldehyde. This has long been a favorite for the treatment of the acute phase of alcoholism. However, it is little more than an effective hypnotic and renders the patient sleepy and drowsy even after awakening. Dosages vary from 5 to 25 cc. orally or 10 to 15 cc. intramuscularly, depending upon the size of the patient. When given intramuscularly, great care must be exercised in seeing that the drug is administered deeply into the muscle, since deposits of this drug more superficially will result in necrosis of the tissue. Paraldehyde has definite drawbacks, in that it is habituating to a great extent, and many alcoholics who have been through the acute phase on numerous occasions will request the drug when entering the hospital. The odor prevalent in the elimination by the lungs renders it unpopular on many occasions. When there is a wish to combine this drug with some of the tranquilizing drugs such as chlorpromazine, it must always be remembered that the chlorpromazine has a potentiating effect on the sedative, necessitating but a fraction of the ordinary dose of paraldehyde.

chotherapy is necessary, the problem that confronts the therapist is to keep the patient from resorting to alcohol during such period of therapy. Chlorpromazine, reserpine, Rauwolfia serpentina, meprobamate, and promazine hydrochloride all can be used for this purpose. The characteristics of these drugs have been described previously, and they may be used during this period of rehabilitation as indicated. Dosages vary and of course are much smaller than when used during the acute phase of the illness. Patients will react differently to these various drugs, and the medicaments can be used most effectively by adapting the therapy to that which suits the individual patient best. It is sometimes of great advantage to use combinations of these drugs, depending upon the effect on the patient. However, there is a percentage of patients who find it difficult to refrain from alcohol even with these tranquilizing medications. With this type of patient, disulfiram is a valuable adjunct.

Disulfiram Therapy

Disulfiram [bis (diethylthiocarbamyl) disulfide], known as TETD or Antabuse, is a drug designed to keep the alcoholic from drinking. Ingestion of alcohol while under this therapy results in an episode of severe and intense illness, which is so disquieting that knowledge of such a reaction acts as an excellent deterrent. Disulfiram itself has very little effect upon the body. Some patients might complain of fatigue, a slight loss of sex potency, an occasional skin allergy, some headache, some malaise, but generally speaking it is tolerated without any difficulty. Occasionally it causes gastric distress. With the ingestion of the slightest amount of alcohol, however, a succession of symptoms occurs that causes extreme discomfort.[11] Within a few minutes of alcohol ingestion, there is a flushing of the face that extends down over the neck and chest and becomes deeper and deeper until the skin is bright red. There is a sensation of great heat in the area, followed by a pounding headache that becomes very severe. The blood pressure rises suddenly with this headache, but within a few minutes there occurs a precipitous drop in the blood pressure, giving the patient a sense of faintness and nausea, sometimes followed by violent vomiting. The patient may break into a cold sweat and often complains of extreme pain in the precordium, simulating a coronary heart attack. The discomfort is very severe and may last from one to two or even four hours, depending upon the amount of disulfiram and alcohol that has been ingested. The patient subsequently falls into a deep sleep, which may last for several hours.

When this drug was first used, it was thought necessary that it be administered in a hospital setting. After the patient recovered from the acute intoxication disulfiram was given and the patient subjected to the alcohol test. He was given 0.5 oz. of whisky and allowed to experience the sensations described. In this way he learned what would happen should he drink alcohol while under disulfiram therapy. For some time now, it has been thought unnecessary to subject the patient to this experience. The mere description of what will happen is sufficient for the average patient to understand the risks involved in drinking alcohol while taking this drug. Where doubt does exist and the patient decides to experiment, only a small amount of alcohol is sufficient to convince him of the effect of disulfiram. It is necessary, however, for the therapist to describe accurately to the patient the risks involved and what will happen, so that there will be no doubt in his mind that drinking alcohol will result in serious consequences. In addition, he is given a card to carry with him, identifying the patient and his physician, explaining that he is under disulfiram therapy and that no alcohol should be administered should he be found in an unconscious state. The description of this procedure is by far, in most cases, sufficient to convince the patient of the seriousness of this type of treatment.

In those cases where the patient does take alcohol while under disulfiram therapy, it is well to know the antidotes that can be used. Recommended measures are putting the patient in shock position and injecting ascorbic acid intravenously. If the patient is unconscious, caffeine and sodium benzoate may be administered intramuscularly. Dextrose and saline infusions are also recommended, as well as plasma, and oxygen when indicated. A good antihistaminic may be administered intramuscularly or intravenously, and diphenhydramine (Benadryl) hydrochloride has been used this way effectively. Another method of counteracting the effects of the disulfiram-alcohol reaction is the administration of chlorpromazine intramuscularly in 50-to-100-mg. doses. This usually induces a calming sleep, and the patient will awaken refreshed without the untoward effects that the reaction usually gives.

Contraindications to disulfiram therapy have been noted. They are cases of severe heart disease, including coronary heart disease, cirrhosis of the liver, epilepsy, drug addiction, psychoses, kidney disease, diabetes, pregnancy, and asthma. Some therapists have used this type of treatment with all of these types of cases without too much difficulty. However, unusual caution must be observed when doing so.

One of the risks in the use of disulfiram therapy is the possible occurrence of a psychosis. It was thought that psychoses occurring while this drug was being used were due to the toxicity of the drug itself. However, now it is believed that it is not the drug but the inability of the patient to escape into his alcoholic oblivion as an outlet for his emotional instability that precipitates the psychotic episode. It has been found that, with further psychotherapy, these patients have been able to take disulfiram again without having any psychotic reaction, even though the dose of disulfiram was exactly the same as before their psychotic episodes. It is wise, therefore, that a psychiatric evaluation be done on the patient before giving disulfiram therapy if severe mental involvement is suspected.

The reaction to alcohol of the patient taking disulfiram is due to the increase of the acetaldehyde content in the blood. In the metabolic breakdown of alcohol into acetaldehyde, acetic acid, carbon dioxide, and water, this process is arrested at the acetaldehyde stage by its contact with disulfiram and the subsequent chemical and enzyme reactions. Since acetaldehyde is a very severely toxic agent, the results that follow ingestion of alcohol are due to the increased acetaldehyde concentration in the blood. The same symptoms can be produced by injecting acetaldehyde intravenously.

Disulfiram has other uses that have proved of value in the treatment of the alcoholic patient. Its original purpose guarantees a period of abstinence long enough for practicing psychotherapy. It can, however, also be used to determine the degree of sincerity that the patient manifests in his willingness to cooperate. After discussing the effects of alcohol ingestion while under disulfiram therapy and the length of time the influence of disulfiram exists in the body, which may be from 24 to 72 hours—in rare instances as long as a week—a disulfiram tablet may be offered the patient. If he swallows it without hesitation, it would be indicative of his motivation and incentive toward abstinence. However, if he demurs, refuses, delays, or in any other way resists taking the pill, it is assurance that he still has many reservations about following through with the rest of his program. The greatest value to the patient on disulfiram therapy is the revelation that he can live without drinking. Very often after long periods of abstinence he can appreciate how much he has proved this fact to himself.

More recently, citrated calcium carbimide has been reported to be useful as a substitute for disulfiram. It has somewhat the same effects, but is said to be devoid of undesirable side-effects sometimes encountered with disulfiram—gastric distress, drowsiness, and others noted previously.[12]

Conditioned Response Therapy

The conditioned response treatment is based upon the theory that the individual patient can be trained to a certain emotional reaction under certain defined situations. This method of therapy has been employed in many areas and reports indicate variable success. In the hands of some therapists, patients respond well to this type of therapy. With others, the success has been questionable. The treatment is carried out by administering to the patient a dose of alcohol to which there has been added some type of emetic, emetine or ipecac. Under controlled conditions, the patient is given the dose of treated alcohol and the ingestion is followed by severe retching and vomiting for some time.[13] The administration is repeated on several occasions. The theory is that, after a number of such experiences, the patient will automatically refrain from drinking alcohol for fear of the consequences. Some therapists have substituted the injection of apomorphine simultaneously with the ingestion of alcohol. This type of therapy must be carried out under controlled circumstances in order to establish the conditioned response. The treatment is usually carried out in an institution where the patient can be watched carefully over a given period of time and the administration controlled with a maximum of environmental influence.

Complications of Chronic Alcoholism

Hallucinosis.—Hallucinosis is characterized by auditory or visual hallucinations, usually auditory. It usually occurs after the patient has been detoxified. The hallucinations are less severe than with delirium tremens. Differentiation from delirium tremens is important and can usually be determined by the orientation that is present with hallucinosis and absent with delirium tremens. Sedation with the tranquilizing drugs until the phase of hallucinosis is passed is the treatment of choice. However, corticotropin in 25-mg. doses given intramuscularly or intravenously every four hours for six doses has proved effective. The panic and fear associated with delirium tremens is usually not present with this complication.

Recently, azacyclonol (Frenquel) hydrochloride in doses of 20 mg. three or four times a day has also been used for this complication. It is specifically valuable for hallucinosis and has been found very effective.

Delirium Tremens.—Delirium tremens is fairly common and occurs after prolonged drinking. It may also occur upon withdrawal of alcohol after prolonged drinking. The characteristics of this condition are intense excitement, delirium, and coarse tremors. It may be accompanied by convulsions of the grand mal type. Present also is marked confusion with disorientation, which differentiates this condition from hallucinosis. Both auditory and visual hallucinations are present as a rule. These hallucinations are extremely vivid and often take the form of animals all over the room and the patient. Bizarre combinations of animal bodies and human heads and vice versa are present. Physical findings usually include dilated pupils, flushed skin, subnormal temperatures (unless intercurrent infection is present), and profuse sweating. Minute petechial hemorrhages of the brain may occur during this stage and often give rise to persistent tremors.

Treatment consists of the measures used for patients in the acute alcoholic state. The tranquilizing drugs have been recommended by many therapists and chlorpromazine and promazine have both been used to advantage.[14] These can be given intramuscularly or intravenously, but in my experience I have found it advantageous to combine them with other sedative drugs when the excitement in the patient is great. Administration of corticotropin in 25-mg. doses at four-hour intervals has also helped in bringing about more rapid recovery. This can be given intramuscularly or intravenously in the dextrose and saline solution.[10] After recovery from the acute delirium, the treatment is continued as in other stages of alcoholism.

Acute Gastritis and Enteritis.—This complication is usually due to chemical irritation of the mucous membrane of the gastrointestinal tract. Mental distress, anxiety, and frustration are usually associated with this irritation. Withdrawal of the alcohol will relieve the symptoms, as will gastric sedatives and bland diet. Drugs used in the usual gastrointestinal cases to reduce motility and soothe the inflamed membranes will also aid in this condition. The use of chlorpromazine and promazine hydrochloride for this condition will often allay the nausea and vomiting that accompany the irritation of the digestive tract membranes. However, it is often necessary to apply psychotherapy also in many such cases to help relieve the symptoms.

Varices of the Esophagus and Cardiac End of the Stomach.—This condition probably occurs much more commonly than is suspected. Its danger lies in the possibility of hemorrhage. Such signs as vomiting of blood, tarry stools, signs of shock, pallor, low blood cell count, or low blood pressure and other obvious evidences of acute hemorrhage must be borne in mind. At the first indication of such signs, immediate treatment should be instituted. The general regimen for acute hemorrhage anywhere may be used here, including complete sedation and quiet for the patient. Intravenous infusions of saline solution may be necessary, as well as transfusion if indicated. Where the hemorrhage continues, use of the Sengstaken or the Patton tube may be indicated. This tube is passed into the stomach and the bulb is inflated to 20 to 30 mm. Hg. The tube is left in place for 20 to 48 hours before deflation. After deflation of the tube, the patient should be observed for 12 hours to make sure that there is no recurrence of the hemorrhage. If no bleeding occurs, the tube may then be removed.

Cirrhosis of the Liver.—Cirrhosis of the liver is one of the very common complications of chronic alcoholism. While it is now recognized that cirrhosis of the liver is not due to the action of the alcohol itself, it is nevertheless one of the sequelae associated with chronic alcoholism. It has now been established that alcoholism is not the only cause of cirrhosis of the liver but that other conditions, which would be responsible for the lack of proper vitamins and minerals in the diet as well as necessary nutritional elements, are the basic cause of this disease. The liver has proved to be a very handy organ and can be subjected to a great deal of abuse before the condition becomes irreversible. Administration of the necessary vitamins and minerals and an adequate diet will usually result in the recovery of the liver to its normal function. However, in extreme cases and in cirrhosis of long duration, the destruction may be so severe that complete recovery is impossible. Proper diet, administration of vitamins and minerals, and in some cases injection of liver extract will help support the diseased organ. In some cases, surgery has been resorted to in order to establish increased circulation to the liver in an effort to relieve the portal system. However, in most cases, supportive treatment will be sufficient to correct this condition.

Less Frequent Complications.—The less often encountered complications of chronic alcoholism are given below.

Pathological Intoxication: Pathological intoxication is a severe reaction to the ingestion of alcohol. It is characterized by a precipitous and almost maniacal response to a comparatively small amount of alcohol. It is theorized that in such cases the alcohol acts as a trigger release mechanism setting off the ability to control the patient's actions. Treatment consists of heavy sedation until the acute phase passes.

Korsakoff's Syndrome: Korsakoff's syndrome is characterized by amnesia and confabulation. The treatment consists of supportive measures. Prognosis for recovery in these cases is very poor. Since it is now believed that this complication occurs as a result of inadequate diet, the necessary nutritional elements, vitamins, and minerals must be supplied in sufficient amounts.

Hemorrhagic Polioencephalitis, Superior (Wernicke's Disease): Characteristics of hemorrhagic polioencephalitis, superior (Wernicke's disease) include limited movements of the eyes due to partial paralysis of the eye muscles. Mental changes include intense excitement, convulsions, and clouding of consciousness, which may be severe enough to end in stupor and coma. There are usually pathological reflexes present with extreme tensions of the muscles. Tendon reflexes are absent. Since this complication is also considered to be the result of deficient nutrition, large doses of thiamine, adequate diet, and vitamin and mineral complements are indicated. Not uncommonly, complete restoration fails to occur. Mental confabulation resembling Korsakoff's syndrome is often a residual effect and may remain.

Marchiafava's Disease: Marchiafava's disease (primary degeneration of the corpus callosum) was once thought to be due to alcoholism. With only 100 cases reported in the literature, it was finally determined that this complication resulted not from the alcohol but from the metallic impurities found in wine as the result of processing.

Acute Lethal Alcoholism: Acute lethal alcoholism is due to ingestion of alcohol to a blood concentration sufficient to cause death. It occurs and acts the same as an overdose of anesthetic, producing death by a complete anesthesia of the vital centers of the brain.

Summary and Conclusions

In treating the chronic alcoholic, factors other than the medical and psychiatric approach must be taken into consideration. The patient's social environment, religious background, employment or industrial situation, and his relationships with family, friends, fellow employees, and others are pertinent factors. His relationships with his local health department, mental health department, Alcoholics Anonymous, and clergy are additional important contributions to treatment. In the chronic alcoholic, we are dealing not only with a sick individual but with that individual in relationship to his environment. In order to treat him adequately, all of these circumstances must be included.

In treating the chronic alcoholic, the cooperation of the patient is perhaps the single greatest factor in addition to the understanding and patience of the attending physician. Such psychotherapy as is necessary can be administered by the average physician who will take the time to understand and help the sick alcoholic. With the advent of the new tranquilizing drugs, the treatment of the acute phase has been greatly simplified. With the use of disulfiram (Antabuse), the patient can remain without alcohol sufficiently long for the interested physician to help him gain insight into his problem. Helping to give the alcoholic a healthy body so as to maintain optimum physical fitness will in itself make him feel better and more capable of meeting the problems that have induced his illness and probably caused it to continue. The physician has in the alcoholic a challenge from which he cannot retreat. To meet this challenge, he requires knowledge, understanding, and patience. If he will develop and use these qualities, the chances of his success with alcoholic patients will be enhanced and the results rewarding.

MEDICINE AT WORK

MUSIC AS A MEDICAL TOOL

ANCIENT "TRANQUILIZER" COMES OF AGE FOR VARIETY OF PATIENTS

Fifteen miles from Boston's Beacon Hill, a dozen men and women one afternoon this month took part in a New England tradition that is over a half-century old. They gave a 45-minute concert of English hand-bell ringing before a sizable audience in Westwood Lodge.

It was no routine affair for the musicians, ranging in age from 18 to 79 years One was an alcoholic; others were suffering from deep depression, psychoneuroses, and schizophrenia. Westwood Lodge is a private sanatorium for patients with nervous and mental diseases. What made the occasion special was that some of the patients, somehow, were responding to the tuned bells when other musical instruments and treatment had failed to crack the shells enclosing their personalities. The sanatorium's medical director, Dr. Martha Brunner-Orne, beamed with delight as "Jingle Bells" and "Silent Night" chimed through the halls and into her office. She said: "It's just wonderful. This is the first time since we started bell ringing that the Christmas party has been devoted to that kind of music."

Hours of boredom for these Dutch patients with tuberculosis ended when the sanatorium director supplied harmonicas, rolled the bedridden players into a room, and started an orchestra Note the director at lower right and the overhead mirror he uses to survey the musicians

Dr. Brunner-Orne, a psychoneurologist, conceived of the bell ringing program one autumn evening in 1954 while at the piano in a duet with her violin-playing husband, Dr. Frank E. Orne, an obstetrician-gynecologist and fellow graduate of the University of Vienna medical school. Since then, officials of other sanatoriums have sought her advice on how they might organize similar projects.

The bell ringing at Westwood Lodge is but an echo of worldwide music that is being sounded again and again for its value as a medical aid. In the Juliana-Oord Tuberculosis Sanatorium at Laren, the Netherlands, 24 men and women suffering from tuberculosis of the bone lie flat on their backs as they present a a harmonica concert. Even the conductor is a patient, surveying his orchestra through a mirror over his head. The medical director, Dr. C. P. H. Teenstra, a director of Rotary International, brought in the harmonicas 15 years ago "just for fun."

At Denver, Colo., a 6-year-old boy plays "The Parade of the Wooden Soldiers," the first piano piece he mastered early in 1955 after an attack of poliomyelitis that left him paralyzed from the neck down in Children's Hospital. On the advice of a physician, Music Teacher Eva V. Welbourne placed the boy's arms in special slings attached to his armchair and pressed down each little finger on the piano keys until at last, after four months, the child's face lit up with the first notes of his own effort. Mrs. Welbourne has devised 20 methods by which students whose upper extremities are variously incapacitated can play the piano. They may use one finger, their elbows, their fists, their knuckles. For arthritics whose hands are clenched, she places a pencil between the fingers or a potato within the painful grasp—as the key striker.

What Does Music Do?

What happens when music—not in itself a cure—is used as a medical tool? For the bedridden patients with tuberculosis in Holland, the blank and boring ceiling scene vanishes in the melodious vibration of hundreds of brass reeds. Bell ringing patients in the Massachusetts sanatorium tend to develop confidence within a group, willingness to accept responsibility, and a music concentration that pushes aside thoughts of their personal problems. And in Denver, Mrs. Welbourne says of her piano students: "They become less handicapped than the man or woman who has two hands and 10 fingers, and does nothing constructive with them."

In the House of the Good Samaritan research hospital for rheumatic fever in Boston, young patients play keyboard instruments, flutes, "tunable beer glasses," and reed organs. Elsewhere, orthopedic and neurological patients are eased into shoulder movements by playing the drum, concertina, cymbals, and trombone.

Thousands of years ago, our ancestors used music as part of their magic healing rites, just as primitives in isolated areas do today. Although music had been used in mental hospitals in this country as early as 1792, it was not until World War II that it became widely accepted as a medical aid, largely because of its use in Army hospitals (there is greatest use now in the 100-odd Veterans Administration hospitals). A half-dozen schools offer four-year courses leading to a degree in "music therapy." Music is used in mental hospitals as an adjunct to shock therapy, hydrotherapy, and lobotomy—and the tonal expert must know how various types of music might affect different individuals.

For example, you can imagine the effect on a patient emerging from anesthesia of the booming of Wagner's "Ride of the Valkyries." Such heavy, dramatic music actually has caused relapses among patients in some hospitals. Well-planned programs, however, may carry rhythmical concertos for crippled children while they struggle painstakingly with finger painting and gay overtures for oldsters in lonely rest homes. The deaf place their finger tips on the instrument being played—and soon are able to coordinate vibration with the unheard or little-heard tones.

Some outstanding work in the field has been widely publicized, such as the case of Horace F., a schizophrenic pianist at Wayne County General Hospital, Michigan, who performed brilliantly on a nationwide CBS broadcast. Still untold are the stories of many other patients. *Etude* magazine observes: "In this age the musical profession treats people, not merely their diseases. And oftentimes, from this standpoint, music is 'good medicine.' "

Music Is Not a Cure

But although music is shown to be of great help in medicine, physicians generally have not been able to accept it as therapeutic in the true sense of the word. Dr. Jules H. Masserman, professor of nervous and mental diseases at Northwestern University in Chicago, says: "Music is only one of many avenues of approach to the patient when words alone, as is often the case, are inadequate. . . . We cannot invoke pompous sounding scientific formulae to the effect that 'rhythm stimulates the thalmus' or 'music reintegrates the functions of the cerebral cortex'; as a moderately well-trained neurologist who has conducted active research in the field I can assure you there is hardly a shread of valid evidence for such formulations."

Nevertheless, Dr. Masserman recognizes music's great value for patients. He has been an officer of the National Association for Music Therapy, whose executive committee also boasts such members as Dr. Karl Menninger of Topeka, Kan., and Dr. Ira M. Altshuler (a pioneer in the field) of the Wayne County General Hospital. It is part of Dr. Altshuler's thesis that music should enter on the mood of the patients. That is, for a maniac the music should be loud and fast, and then gradually become more subdued to bring about a similar response in the patient.

Dr. Emilian A. Gutheil, a New York City psychiatrist, sees great promise in music therapy, but he insists that it does not exist today. Says Dr. Gutheil: "The interest of the public in the problems of music therapy is tremendous, but so far no institution has undertaken the painstaking and difficult task of sifting those empirical findings which are scientifically acceptable. Most of the existing research groups are scattered, split in their aims, jealous of recognition, impatient of results, and too eager to obtain therapeutic tools to devote enough effort to tedious step-by-step research. We must arrive at a safe margin of predictability regarding causes and effects if we wish to 'write prescriptions' for therapeutic music selections."

The orchestra at Downey Veterans Administration Hospital rehearses for part of a recreation program for patients.

Prescriptions might very well be written in song titles if the coordinated-research challenge flung by Dr. Gutheil is taken up in earnest by the medical profession. Does the cold-compulsive like Bartok, Dixie, or Rock 'n' Roll? Would Mozart or Loesser cause more stability, better recovery, or more confusion—and with what type of patient? The questions are many, the research field is vast, the evidence is everywhere.

Dr. Wilma Donohue, gerontologist at the University of Michigan, tells of a 90-year-old woman completely out of touch with her surroundings who lived briefly in the present—smiling as a chain of associations was set up by a waltz being played on an accordion. President Eisenhower prescribed some of his own "heart medicine" from a sickbed in Denver last year when he called for selections from Brahms and Bach. Last month 1,200 guests of the women's auxiliary of the Chicago Medical Society watched as 50 patients in a VA hospital demonstrated their concept of music's role in physical and mental rehabilitation.

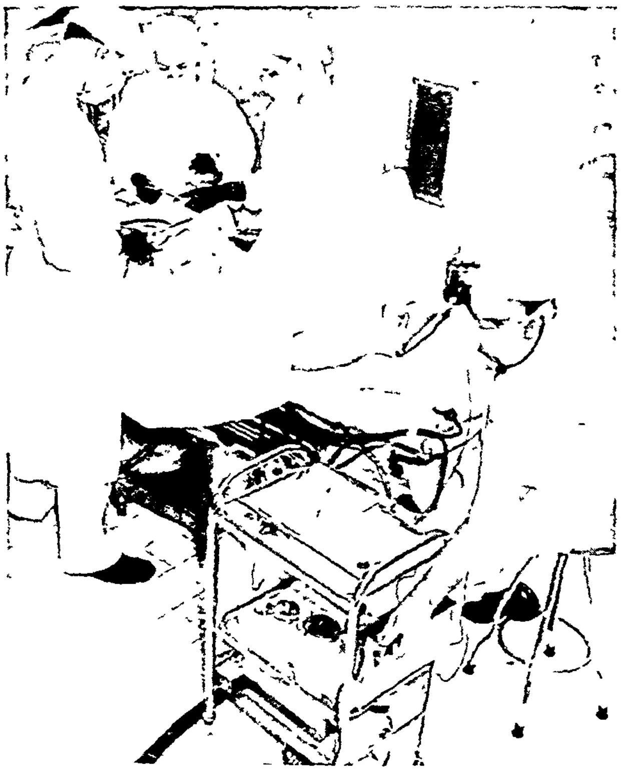
Doctors Are the Connoisseurs

There may be some significance in the fact that physicians as a group are among this nation's leading music connoisseurs. The *Saturday Review of Literature* reports: "If you took a random slice through the followers of high fidelity in any community there would be several times as many doctors in it as their number in the community as a whole would seem likely." The attendance of physicians at a Seattle Symphony Orchestra performance during the A. M. A. Clinical Session last month was greater than at any other single meeting of doctors in that city. Doctors' orchestras are making music in New York, Chicago, Detroit, San Francisco, St. Louis, and Washington, D. C. The Los Angeles Doctors' Symphony has a concert scheduled for this coming Jan. 12.

These medical men are realizing that for centuries music has been a "tranquilizer" to the healthy as well as to the sick—whether the subject produces it on an instrument or simply listens to it. Dr. Arthur Abramson, chief of physical medicine and medical rehabilitation at the Bronx Veterans Administration Hospital, claims that in some operating-room situations music may help the surgeon, the nurse, and other attendants—as well as the patient—particularly when it is played during the administration of anesthesia.

Music is piped into six operating and preoperative rooms of Billings Hospital in Chicago from a sixth-floor studio. If they wish, patients may hear their favorite selections through stethoscope-type earphones (the night before an operation, an anesthesiologist notes the patient's choice of "music for surgery"—classical, semiclassical, or pops). Officials at Henrotin Hospital, also in Chicago, still talk about the cesarean section performed on a frail little woman several years ago—with music as the chief sedative. It took three days of planning to devise the special four-hour FM broadcast musical program so that it would coincide with various phases of preoperative procedure and actual surgery.

Even at the end, music sets the tone. Not long ago in a large Midwest hospital, one physician gently closed a door on the quiet strains of a violin concerto. A young girl patient inside the room was dying, a hopeless case. Overcome with compassion, he wrote this letter to the local broadcasting station: ". . . despite extended and severe pain she had become serene and smiling during those last days filled with music in the air. Your music is a Godsend to our cases."



In a University of Chicago Clinics operating room, music with anesthesia is audible to the patient but silent to the surgeon. The anesthesiologist is also provided with a set of earphones to monitor the volume of the music for the patient.

CLINICAL MEETING AT SEATTLE

Medical ethics, veterans' medical care, radioactive isotopes, continuance of the A. M. A. interim session, hospitalization for patients with alcoholism, and a report of the Committee on Medical Practices were among the wide variety of subjects acted on by the House of Delegates at the American Medical Association's 10th Clinical Meeting held in Seattle, November 27-30.

Medical Ethics

The subject of greatest interest was the proposed 10-section revision of the Principles of Medical Ethics submitted at the June, 1956, Annual Meeting in Chicago, where final action was deferred until the Clinical Meeting. The proposed short version of the Principles was resubmitted to the House with some changes based on suggestions received since last June by the Council on Constitution and Bylaws. The House of Delegates, however, decided to refer the matter back to the Council on Constitution and Bylaws for further study and consideration. The reference committee report adopted by the House included the following statements:

"Careful consideration was given to the Preamble and the ten sections of the proposed Principles. The Preamble and seven of the ten sections appear to be acceptable in their present form.

"Sections 6 and 7 were not acceptable as presented either to the group which appeared at the hearing or to your reference committee.

"Out of the general discussion the reference committee received the crystallized opinion that at least four areas needed more specific attention in Sections 6 and 7. These are:

"(1) Division of fees;

"(2) The dispensing of drugs and appliances;

"(3) The corporate practice of medicine;

"(4) Greater emphasis concerning the relationship between physicians and patients.

"In addition, the reference commitee felt that the wording in Section 10 could be improved if amended to read as follows:

" 'The responsibilities of the physician extend not only to the individual but also to society and deserve his interest and participation in activities which have as their objective the improvement of the health and welfare of the individual and the community.'

"In view of the above your reference committee believes that the proposed Principles of Medical Ethics should be referred back to the Council on Constitution and By-Laws for further study and consideration of the above stated principles.

"In the short space of time at our disposal and in view of the importance of the subject, your reference committee did not deem it wise to attempt to properly phrase these concepts.

"We would also recommend that if possible this study be completed at least six weeks prior to the June session and that the new version be published in THE JOURNAL in order that all interested physicians might have an opportunity to comment thereon."

Veterans' Medical Care

The House revised A. M. A. policy on veterans' medical care by endorsing in principle the following paragraph suggested by the Council on Medical Service:

"With respect to the provision of medical care and hospitalization benefits for veterans in Veterans Administration and other federal hospitals that new legislation be enacted limiting such care to veterans with peacetime or wartime service whose disabilities or diseases are service-incurred or aggravated."

This action eliminates the temporary exceptions that were made in the June, 1953, policy regarding wartime veterans who are unable to defray the expenses of necessary hospitalization for non-service-connected cases of tuberculosis or psychiatric or neurological disorders. In making the policy change, the House approved this supplementary statement:

"We recognize the laws and administrative extensions of the law that are now in operation. We feel that under the circumstances it will be to the best interests of the public in general, and veterans in particular, if medical societies, county and state as well as national, develop committees to assist in guaranteeing VA hospital admission to service-connected cases. While the present law exists, we should help assure that veterans whose illness constitutes economic disaster will not be displaced by those suffering short-term remediable ills which, at the worst, constitute financial inconvenience."

In another action concerning veterans, the House passed two resolutions condemning as unlawful the practice of those Veterans Administration hospitals that admit patients covered by workmen's compensation insurance or by private health insurance and that render bills for the cost of their care. Both resolutions requested the A. M. A. to take action to bring about a discontinuance of such practices by VA hospitals, and one of them instructed the Association's Secretary to obtain from each state testimony or records of each known case that violates VA Reg. 6047-D1.

Radioactive Isotopes

The House rescinded the June, 1951, action that limited the hospital use of radium and radioactive isotopes to board-certified radiologists by approving a new policy statement, which says:

"(1) In any hospital in which a patient is to receive radium or the products of radium or artificially produced isotopes, there should be a duly appointed

Committee on Radium and Artificially Produced Radioisotopes of the hospital professional staff. This committee should include, but not necessarily be limited to, the following qualified physicians: a radiologist, a surgeon, an internist, a gynecologist, a urologist and a pathologist. This committee should have available such competent consultation of other physicians and scientific personnel as may be required by it. Where this is not practicable, the hospital staff should consult the nearest Committee on Radium and Artificially Produced Radioisotopes.

"(2) In any hospital, the use of radium or its products and artificially produced radioactive isotopes for diagnostic or therapeutic purposes shall be restricted to qualified physicians so judged by the Committee on Radium and Artificially Produced Radioisotopes of the professional staff to be adequately trained and competent in their particular use.

"(3) It is recommended that procurement, storage, dosimetry control and inventory of all radioactive isotopes for the use of the hospital staff and radiological safety control be centralized, and, where administratively possible, centralization be located in the Department of Radiology.

"(4) It is recommended that the Board of Trustees assign to the appropriate council or committee the continuous study of the problems of radiological safety control in the use of radium and its products and artificially produced radioactive isotopes for diagnostic or therapeutic purposes."

Hospitalization for Alcoholics

To implement educational approaches to the problem of alcoholism, the House approved a statement submitted through the Board of Trustees by the Council on Mental Health and its Committee on Alcoholism. The House also recommended that the statement be brought to the attention of the Council on Medical Education and Hospitals, the Joint Commission on Accreditation of Hospitals, and the American Hospital Association. The statement includes the following section:

"The Council on Mental Health urges hospital administrators and the staffs of hospitals to look upon alcoholism as a medical problem and to admit patients who are alcoholics to their hospitals for treatment, such admission to be made after due examination, investigation and consideration of the individual patient. Chronic alcoholism should not be considered as an illness which bars admission to a hospital, but rather as qualification for admission when the patient requests such admission and is cooperative, and the attending physician's opinion and that of hospital personnel should be considered. The chronic alcoholic in an acute phase can be, and often is, a medical emergency."

Committee on Medical Practices

In approving a progress report of the Committee on Medical Practices, the House amended one of its directives to read as follows in order to remove any legal objections:

"The A. M. A. representatives on the Joint Commission on Accreditation of Hospitals be instructed to stimulate action by that body leading to the warning, provisional accreditation, or removal of accreditation of community or general hospitals which exclude or arbitrarily restrict hospital privileges for generalists as a class regardless of their individual professional competence where such policies adversely affect the quality of patient care rendered. Any action taken should be only after appeal to the Commission by the county medical society concerned."

The House also approved a recommendation by the Committee on Medical Practices that a study group be formed to consider the best background preparations for general practice, and it urged that such action be implemented as soon as practicable.

Miscellaneous Actions

Among many other actions on a wide variety of subjects, the House of Delegates also:

Pledged full support of President Eisenhower's people-to-people program as a means of promoting understanding, peace and progress;

Directed the Board of Trustees to continue its investigation of the practicability of developing a statement of A. M. A. policies and to arrange for the periodic publication of revised versions of such a policy statement;

Noted with pride the good work being done by the 74,348 members of the Woman's Auxiliary, as reported to the House by Mrs. Robert Flanders, President;

Directed the Councils on Pharmacy and Chemistry and on Foods and Nutrition to conduct a joint study of all presently available information concerning the fluoridation of public water supplies and to present a documented report of findings and recommendation at the December, 1957, meeting;

Urged all physicians to participate actively in the formulation of medical policy for prepaid medical care plans that are under physician direction or sponsorship;

Changed the bylaws to extend service membership to reserve officers on extended active duty with the defense forces and the U. S. Public Health Service;

Changed the bylaws relating to transfer of membership so that an active or associate member of the Association who moves his practice to another jurisdiction may continue his A. M. A. membership by applying for membership in the constituent association in his new jurisdiction, subject to a two-year limit on approval of his application;

Changed the bylaws so that the election of officers may take place at any time on the fourth day of the annual session, instead of being restricted to the afternoon of that day;

Passed a resolution calling for the American Medical Association to join with the American Hospital Association and the American Institute of Architects in their proposed study of hospital design and construction;

Approved the principle of a voluntary reduction in the self-assigned quota of interns as printed in the 1956 handbook of the National Intern Matching Program; and

Instructed the Board of Trustees to accentuate cooperation between the American Medical Association and the American Bar Association to the end that a bill of the Jenkins-Keogh type be enacted at the next session of Congress.

Medical School Support

The American Medical Association and four of its constituent societies—California, Arizona, Utah, and New Jersey—contributed nearly $300,000 to the nation's medical schools. At the opening session of the House of Delegates the American Medical Association announced that it was making another gift of $125,000 to the American Medical Education Foundation, bringing to $343,000 the amount that the A. M. A. has contributed to the foundation this year. In addition to the A. M. A. contribution, four state medical societies presented checks to the foundation, which will bring the contributions from physicians and medical societies to more than 1 million dollars for 1956. The states and their amounts follow: California, $132,981; New Jersey, $25,000; Utah, $11,870; and Arizona, $3,695. The practicing physicians of the nation have to date contributed nearly 6 million dollars to the foundation since it was founded in 1951. These contributions, going to the 82 medical schools in this country, can be used as the schools see fit.

Registration exceeded all expectations. The total registration was 6,282. This included 2,813 physicians. Last year's Clinical Meeting in Boston drew a total of 8,637, including 3,779 physicians. At Miami in 1954, the total was 7,707, including 3,253 physicians. A nine-page mimeographed summary of what the House did was mailed by the Secretary, Dr. George F. Lull, to all delegates and state society officers direct from Seattle, and the proceedings will be published in THE JOURNAL.

While there were many visitors who had reason to regret the fog that interfered with flying schedules, none had reason to complain about the renowned hospitality of the northwest area of the United States. This was a memorable meeting, and it ended with a note of deep appreciation of the Seattle doctors and their neighboring colleagues for the success of the meeting. No doubt many of the visitors already are planning their next trip to enjoy again the beauty of this area and what its people have to offer.

THE SCIENTIFIC ASSEMBLY AND THE SEATTLE MEETING

An unusual degree of enthusiasm marked all activities of the Scientific Assembly at the Seattle Meeting from the time Governor Arthur B. Langlie of Olympia, Wash., opened proceedings Tuesday morning until the lights were turned out Friday noon. The entire scientific meeting was held in the Civic Auditorium, making it possible for the visiting physician to go from panel discussions to lectures or to television, motion pictures, and demonstrations in the Scientific Exhibit with a minimum of delay. Various portions of the program progressed simultaneously and continuously, with only a slight lessening of the tempo during the noon hour.

The 20 panel discussions were popular, with crowded sessions most of the time. The subjects were practical, such as prenatal care, postpartum problems, pelvic pain, bleeding in pregnancy, problems of the aging, hypertension, management of low back problems, diabetes, and tranquilizing drugs. The moderators and participants of all panels were well versed in their particular subjects.

One hall was devoted entirely to lectures, which included 46 subjects covering the whole range of medicine. Many of the lecturers were from the Seattle-Portland area, making it possible for physicians from other parts of the country to obtain a comprehensive idea of the practice of medicine in the Pacific Northwest. The program included, however, outstanding men from the Middle West and the Eastern Seaboard, making this activity alone worth the trip to Seattle.

Color television was conducted with the cooperation of Smith, Kline & French Laboratories. The program, which originated at Doctors Hospital, was presented to capacity audiences at Civic Auditorium, the two-way conversations between meeting hall and operating room being especially valuable contributions. Wet clinics were conducted each morning and dry clinics each afternoon.

This motion-picture program, from the point of view of sustained interest, was one of the most successful ever conducted at a meeting of the American Medical Association. Each afternoon films were shown in Civic Auditorium, with a total of 24 titles. On Tuesday evening two films were shown at the Olympic Hotel, the first of which, titled "The Medical Witness," was presented with the cooperation of the Wm. S. Merrell Company. This was a special attraction for the legal profession as well as the medical profession and was introduced by Mr. David F. Maxwell, president of the American Bar Association. The attendance was so great that a second showing was required. Meanwhile, in an adjacent room, the film "Monganga" was presented with the cooperation of Smith, Kline & French Laboratories. This picture also attracted a capacity audience.

The Scientific Exhibit featured demonstrations continuously in 98 exhibit booths. Outstanding interest was evinced in a special exhibit on the history of medicine in the Pacific Northwest under the direction of Dr. Willard F. Goff, Seattle. The special exhibit on fractures under the guidance of Dr. Ralph G. Carothers, Cincinnati, and manikin demonstrations on problems of delivery, arranged by Dr. Charles Franklin, were always popular. Special lectures on "The Practice of Public Health and Medicine in Alaska," by Dr. Charles R. Hayman, Juneau, were especially attractive. The other 94 exhibits all merit special citation that is impossible to give. The authors were continuously present, making it possible for the visiting physician to discuss his problems and to partake in a real course of graduate medical education.

The smoothness with which all scientific activities were carried out was evidence of the meticulous care rendered by the local committee in making arrangements. Dr. Hale Haven, chairman of the subcommittee on scientific program, established an office in the Civic Auditorium, where he was continuously on duty to ascertain that all participants were present at the proper time. Dr. F. A. Tucker, chairman of the subcommittee on television, was in two places at the same time—the hospital and Civic Auditorium. Dr. Wilbur E. Watson, chairman of the subcommittee on transportation, faced an almost impossible traffic situation, with a bus strike and an insufficient number of cabs, but finally arranged special buses between the hotels and the auditorium. Other subcommittees likewise performed outstanding service. Publicity, under the direction of Dr. Earl R. Sanderson, was the best ever at a Clinical Meeting, while the entertainment, under Dr. Sydney J. Hawley, was something that everyone present will long remember. The Woman's Auxiliary, under the general chairmanship of Mrs. J. Lester Henderson, arranged a continuous program of activities for wives of physicians, ending with the special concert of the Seattle Symphony Orchestra for both physicians and wives, presented with the cooperation of Winthrop Laboratories. Dr. M. Shelby Jared, general chairman of the committee on local arrangements, overlooked no detail in making the meeting an outstanding success.

FEDERAL MEDICAL SPENDING

As physicians begin the new year, they, like most persons who earn a living, ponder the subject of income tax. At this particular time, however, most consideration is given to how much tax is due and very little thought to what it is due for. The American Medical Association's Washington Office has determined, with figures from the Bureau of the Census, that this year the average wage earner in the United States will pay about $38.72 to finance just the federal government's health and medical operations. Even with more persons now employed, this is $4.40 more than last year. If we consider the entire family of the wage earner, it will be paying $54.61 for federal medical services. Perhaps a little philosophical pondering is in order for the average physician to see just how his estimated 1956 federal medical "bill" will be spent.

About one-third of the more than 2.5-billion-dollar total of federal medical spending goes to operate the Veterans Administration, and the VA's largest single expenditure supports 121,865 hospital beds each day. Many of these are used for treatment of non-service-connected conditions. The costs of administering and supplying medical care to veterans are slightly greater than the entire medical costs of the Department of Defense, including all three branches of the armed forces. The third agency in the nine-figure category (spending over three-quarters of a billion dollars) is the Department of Health, Education, and Welfare. This comprises the medical aspects of the Public Health Service, the Social Security Administration, the Food and Drug Administration, the Office of Vocational Rehabilitation, and even the Office of Education. In actual practice much of the money covers the Hill-Burton program, the National Institutes of Health and their grants program, and grants to the states for general public health activities and communicable-disease control.

The remaining 170 million dollars supports medical activities of the Federal Civil Defense Administration, the Atomic Energy Commission, foreign health operations, and various medical programs of the cabinet-level departments. Medical care extends from the Federal Employees Health Program to coverage of residents of the Panama Canal Zone.

Many of these activities are obviously necessary to maintain this country's unsurpassed health standards, and undoubtedly research programs will pay rich dividends in procedural and scientific discoveries. Do we, however, as taxpayers as well as practitioners of medicine with a scientific background, understand the *raison d'être* for all federal medical services? Can any of the present health programs now in existence be questioned? Is the average physician contributing each month to pay for health activities that are being duplicated or that are not defensible?

Whether too much is wasted, or not enough expended, is something too difficult for any one individual to evaluate. Fortunately for all the country's taxpayers, the American Medical Association's Council on Medical Service maintains a Committee on Federal Medical Services, the prime concern of which is to educate physicians as well as the lay public on the broad scope of nonmilitary medical programs now practiced by the federal government. As one example, recent publications of this committee have served to show how over 6 million dollars is spent in the Panama Canal Zone in providing all phases of medical care to anyone, whether a resident-employee of the federal government or a person just in the Canal Zone for business or pleasure. In this particular United States community, the type of care as well as the fees are completely regulated by the government. Another example of public-fund expenditures is the medical portion of the International Cooperation Administration (known as Point 4), where almost 30 million dollars is spent organizing national and local health services in foreign countries. This money is in addition to the almost 5 million contributed to the World Health Organization and its Latin-American division, the Pan American Sanitary Bureau.

An evaluation of federal medical spending must include not only how much but, of equal importance, the precise use of each dollar. The total cost of federal health services is a billion dollars more than it takes to run the Commerce Department, and a half-billion more than all the expenses of the Department of Agriculture. It is significant that, as physicians pay their share of the public medical bill, they, because of their professional training and experience, at the same time are attempting to evaluate whether all citizens are getting their money's worth.

MUSIC THERAPY

Although music has been used as an adjunct to therapy in one form or another for thousands of years, scientific study of the relation of music to healing started about 1900. Music is no longer used to exorcise evil spirits, but the use of background music as an adjunct to physical medicine, dentistry, the induction of general anesthesia, and operations performed under local, spinal, or regional anesthesia is well known. Important as this and other passive uses of music therapy are, an even more important aspect of this form of treatment is found in active participation by the patient. Such a program finds its greatest usefulness in the treatment of patients with mental illnesses but may also be extended to a variety of other patients. Trained music therapists are being sought on an ever-increasing scale by the more progressive large general hospitals to aid in general rehabilitation programs. (Elsewhere in this issue (page 1619), "Medicine at Work" presents a detailed report on the use of music as a medical tool.)

---

1. Gilliland, E. G.: Music Therapy in Rehabilitation, Hospital Manag. **81**: 46-48 (April) 1956.

On the passive side, music, properly selected for the needs of the individual patient, releases tensions and allays fears. Thus it has been found that, when it is used in the dentist's office or in the hospital operating room, music reduces the amount of preanesthetic sedation and local or regional anesthetic required. For the chronically bedridden patient it can provide a pleasant escape from boredom. On the active side, music helps mental patients to develop desirable attitudes and behavioral patterns and promotes self-confidence through self-expression; it provides the discipline of orderly activity, promotes memory, increases the span of attention and concentration, and encourages socialization and teamwork. For the patient with any disease of the musculoskeletal system, playing an instrument can be used to develop certain weakened muscles, and marching or dancing to an accompaniment may be used to improve coordination.[1] Because sounds may disturb some patients and some kinds of music may have an unwanted effect on others, all active music therapy should be conducted in a soundproof area away from the wards and music in the wards with few exceptions should be provided through individual headphones.

Just as in our schools those who are most in need of physical development often derive little benefit from the physical training program, being excluded from the teams that have become the focal point of the programs, so too those who are most in need of encouragement in musical expression are not allowed to play in the orchestra or band and must participate chiefly as listeners. The aims of music therapy in a hospital are the very antithesis of such a situation. Those who need music therapy are given every encouragement, and care is taken to emphasize the pleasurable aspects and minimize the drudgery. This may result in early performances that are musically pathetic, or even painful, but therapeutically helpful and subject to great improvement if the therapist is endowed with patience and a true desire to help the sick or handicapped. In general hospitals where an active music therapy program is in operation, concerts given by patient bands and choruses are usually preferred to those by professional groups from the outside. This fascinating field is one that has already attracted many volunteer workers. Others could do much to increase present participation in such programs.

MEDICAL CARE FOR THE NEEDY

While it has been said over and over again, it must be repeated once more—if doctors do not participate in the planning of medical care programs, they will eventually be practicing under conditions forced on them by nonmedical administrators, who have no understanding of the practice of medicine, local problems, or existing resources. Recent amendments to the Social Security Act, to become effective next year, will inaugurate an additional and at the same time separate program of medical and "remedial" care for those persons now taken care of by established public assistance programs. Many state governments are already formulating plans to take advantage of the extra grant-in-aid money this expanded federal program will allow them. It is not too early for the medical profession to ascertain who in state and local government will be responsible for administering this particular plan and to confer with these officials in order to arrange agreement between those who will superintend the program of medical care to the indigent and those who must actually provide the services.

In 1950, the Social Security Act was amended to permit states to utilize a "pooled fund" for providing medical care to the indigent. Under this plan the state deposited a specific amount of money in its medical care fund every month for each person covered by the plan. The total amount was based on the number of assistance clients and was used to finance medical care for all these persons. This system provided for medical care graduated to suit individual medical needs. It also allowed direct payments to hospitals and physicians instead of to the patient, who might not pay his bills if some other need seemed more urgent at the time his grant was given him.

The 1956 amendments affecting the assistance program formally separate federal grants-in-aid allotted for medical care from funds allocated to the four basic public assistance programs. "Public assistance," as commonly used, denotes the four federally aided assistance programs administered by the states: Aid to the Blind, Aid to Dependent Children, Old Age Assistance, and Aid to the Permanently and Totally Disabled. In addition, there are the "medically indigent" and the "general assistance" clients (insufficient income for medical care, or living expenses, but ineligible for a federally aided program). The new changes in the law not only require a separate fund for medical care, in contrast to the old method of including it in the total assistance program, but further require a fund solely for the use of vendor or insurance payments, depending on how the medical care is provided by the states.

A state does not have to participate under these new amendments, but, if it does decide to accept the increased federal money for providing medical care to its indigent, it will have to set up a formal program defining methodology. Pooled fund arrangements now in existence will no longer be eligible for federal aid; all direct payments to vendors of medical care must either come under this new program and its applicable rules or be entirely state-financed. If, however, a state does decide to participate, it is free to plan local fee schedules, capitation-payment arrangements with physicians and hospitals, or even prepayment plans on a contractual basis with state and county medical associations.

Because many physicians are accepting a responsibility to understand medical programs before they are implemented, rather than to suggest changes after the programs' inauguration, many medical care plans for the indigent function quite smoothly for all parties concerned. The Committee on Indigent Care of the American Medical Association's Council on Medical Service is investigating all aspects of the effect the social security amendments will have on medical care and is available to assist any state or local medical society professing an interest in the potentials of this new federal legislation.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

The 10th A. M. A. Clinical Meeting, held in Seattle last month, was exceptionally interesting and educational. The scientific program was excellent, and the physician registration was very good. For those in attendance, the postgraduate workshop of lectures, panels, television, motion pictures, and exhibits provided plenty of new ideas and procedures, and each physician was able to return to his practice with a larger fund of medical knowledge.

Special credit for outstanding work on the meeting should go to the local committee on arrangements and its general chairman, Dr. Shelby Jared; the Washington State Medical Association and its officers and staff; the state chairmen of Idaho, Oregon, Montana, and Alaska; and all those who worked out the details and who served the visiting physicians, their wives, and guests with boundless amounts of Northwest hospitality.

I am happy, too, that the newspapers and radio and television stations again did a superb job of covering the scientific sessions, the deliberations of the House of Delegates, and the various awards made during the meeting. While the Clinical Session was performing its function of getting "what's new" to the practicing physician, the communications mediums were relaying this good story of American medicine to the general public.

In my address to the House of Delegates I tried to emphasize the importance of patient and professional freedom and the need for unity, alertness, and action within our profession. I also urged that the medical profession do everything in its power to help reverse any trend toward government encroachment in the practice of medicine. I sincerely believe every one of us must talk about these three issues every time we have an opportunity to discuss them. They are vital issues for medicine, the patient and our nation.

Recently in Havana, at the World Medical Association meeting, Dr. Rolf Schloegell of Germany called freedom of the patient and the freedom of the medical profession "interacting and interdependent" freedoms and urged all doctors to assume a duty of preserving them. In this I heartily concur.

For a free people the freedom to select a medical adviser is next to the free choice of a spiritual adviser. Both should be held inviolate, and any attempt, however small, to infringe upon them must necessarily be looked upon as a move to endanger our democratic form of government.

We cannot shun our role in preserving and strengthening these freedoms. As Dr. Schloegell has said, "both freedoms are dependent on each other. As a matter of fact, one is the prerequisite condition of the other: Where there is no freedom for the patient, there can be no freedom for the medical profession, and where the medical profession has no freedom or loses it, the patient will not be able to feel that he is free himself."

Our profession does not demand "unbridled and boundless license without measure or purpose," but it does ask for freedom of choice by patients, freedom in the conduct of medical treatment, freedom of prescription, and freedom from supervision by laymen. These are medicine's four fundamental freedoms as given by Dr. Schloegell. Without them the proper patient-physician relationship cannot be created or maintained and the medical care of the patient cannot be on a private, person-to-person level.

Besides being in the best interests of the medical profession, these freedoms are in the best interests of patients, for they assure the American people of the best possible medical care. Our positive, continuing task then is to keep these freedoms. I believe one of the best ways to do so is to practice medicine with plenty of personal warmth and understanding. Let us not rely solely on our scientific skills in treating the sick. Let us combine science with the enriching forces of sympathy and personal concern. All of us should remember that new drugs, instruments, and skills are constantly replacing the old; but tender, loving care can never be replaced.

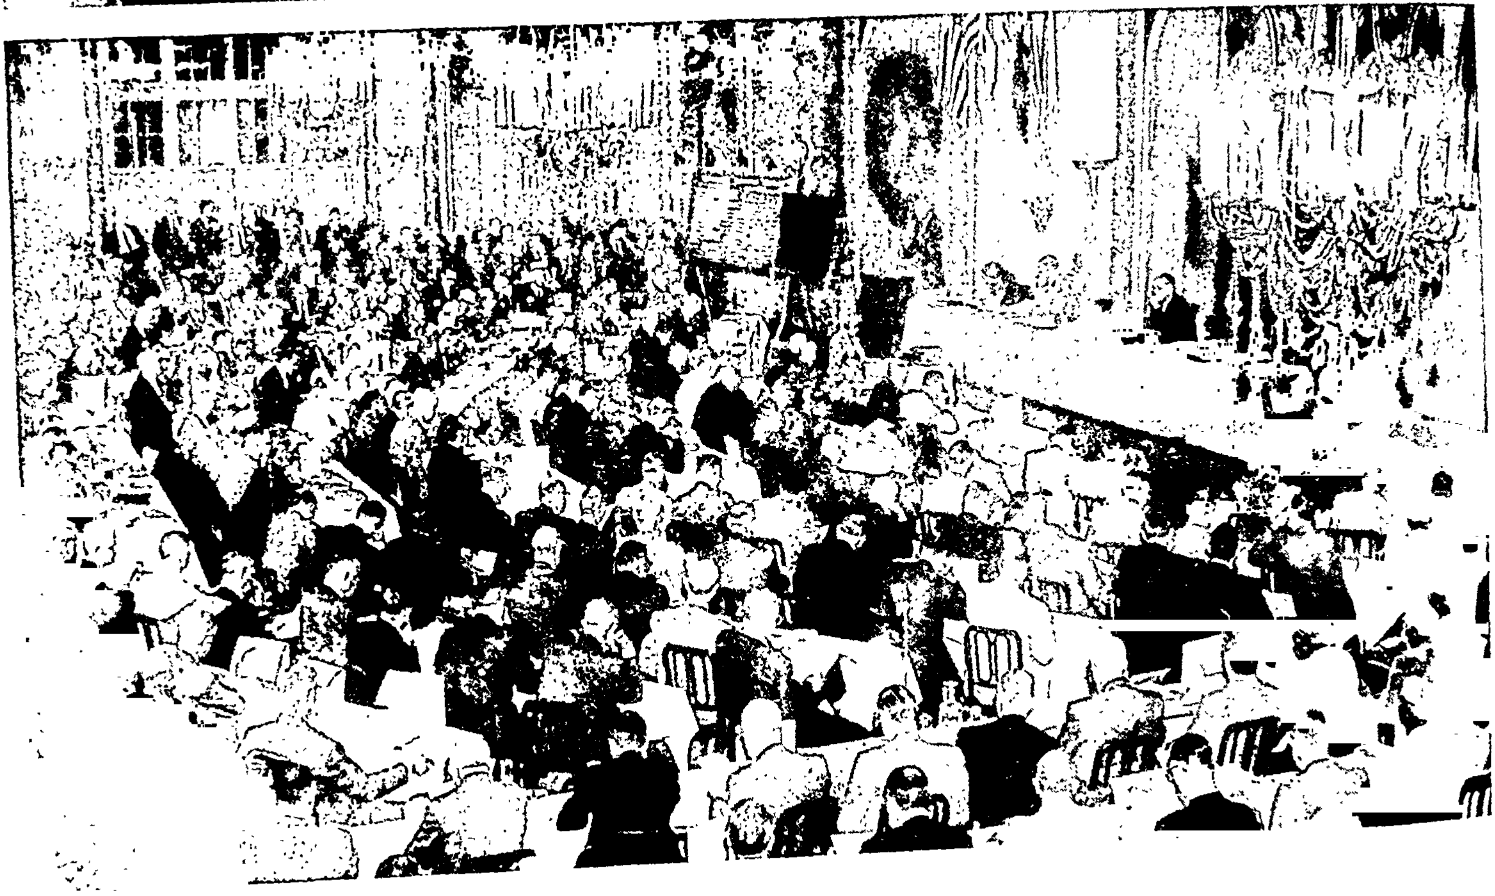
We can bolster the four freedoms of medicine by giving tender, loving care in generous quantities to all our patients. For the patient it is a medicine that works wonders in its own mysterious way. If we dispense it daily to all our patients, it will demonstrate the absolute necessity for the freedom of the patient and the freedom of medical practice, and the resulting good will among patients will be more than enough to deter, defeat, and/or shatter any force seeking to interfere with these freedoms.

DWIGHT H. MURRAY, M.D., Napa, Calif.

Seattle Meeting

Left, early morning registration as physicians entered the Civic Auditorium to attend the opening general assembly.

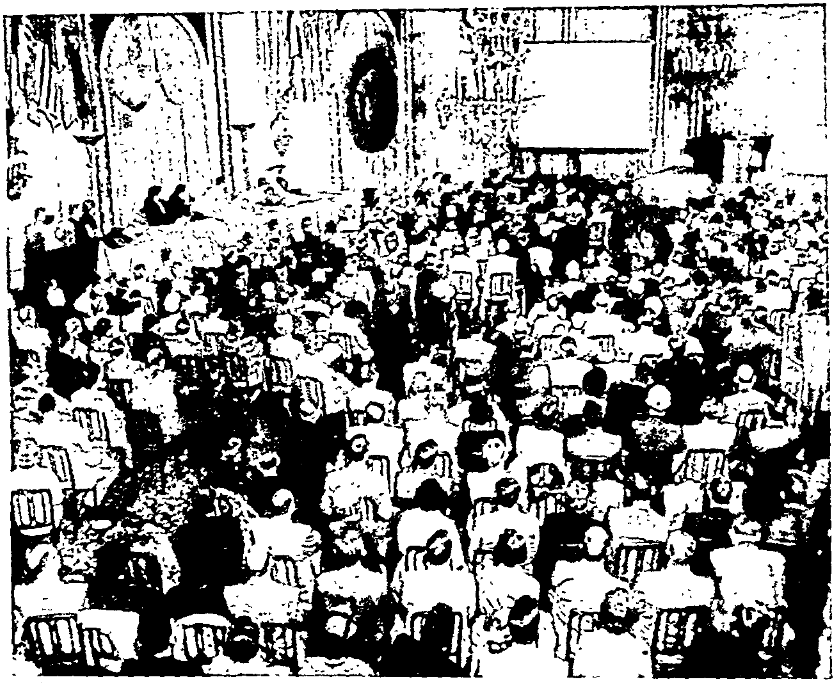
Below, the House of Delegates convened in the Spanish Ballroom of the Olympic Hotel.



Below, typical of the reference committees that study resolutions presented to the House of Delegates is the Reference Committee on Insurance and Medical Service. These committees report their studies back to the House of Delegates.

Among pre-session activities was the meeting of the A. M. A. Council on Constitution and Bylaws. Mrs. Bess Spies McDonald takes notes, as members discuss items on the agenda. Others (left to right) are Drs. Louis M. Orr; E. Vincent Askey; Floyd S. Winslow; B. E. Pickett Sr., Council Chairman; Warren W. Furey; and Walter E. Vest.

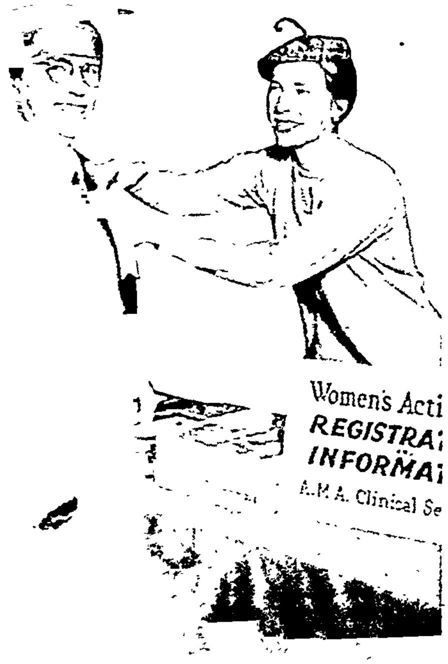
Above, a capacity-plus audience at the premiere showing of the A. M. A.'s new medicolegal film, "Medical Witness," at the Olympic Hotel.



Left, over 700 physicians and guests attended the NBC-TV showing of "Monganga," the latest in the Smith, Kline & French series on the "March of Medicine." The film, made in Africa, shows a missionary physician in practice in the Belgian Congo. It was broadcast in black-and-white and in color across the nation.

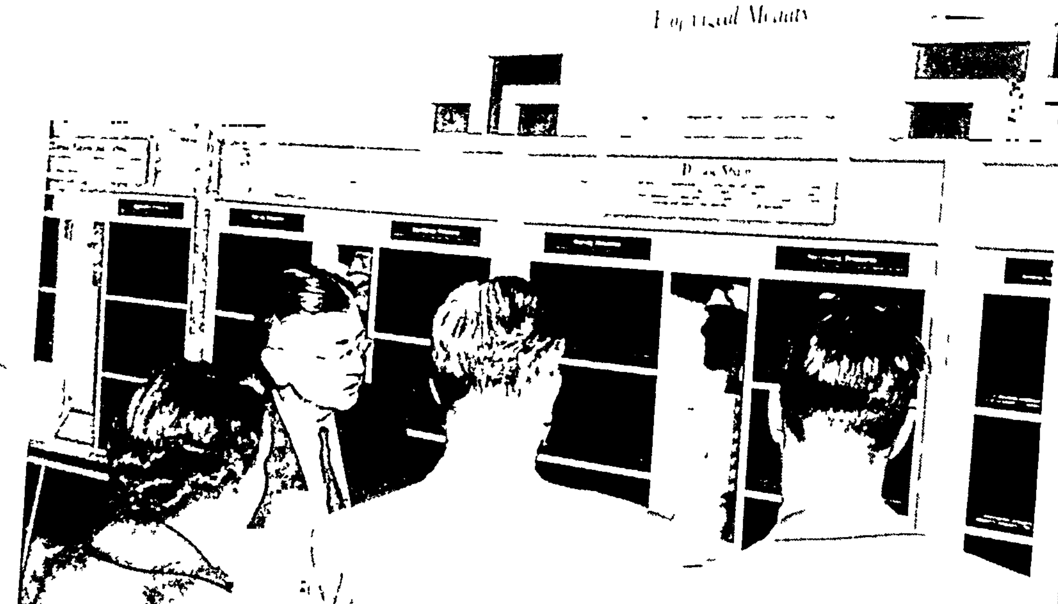
Below, at the opening general assembly of the Clinical Session, Dr. M. Shelby Jared (right), Seattle, general chairman of the local committee on arrangements, welcomed the morning speakers (left to right), Dr. James H. Berge, president, Washington State Medical Association; Arthur B. Langlie, governor of the state of Washington; Dr. Dwight H. Murray, A. M. A. President; Gordon A. Clinton, mayor of Seattle; and Dr. Elmer Hess, immediate A. M. A. past-president.

Below, Mrs. Howard K. Scatliff, Chicago, was an early registrant at the Woman's Auxiliary desk at the Hotel Olympic. Mrs. Clayton Wangeman, Seattle, representing the Woman's Auxiliary to the Washington State Medical Association, pins on an official badge.



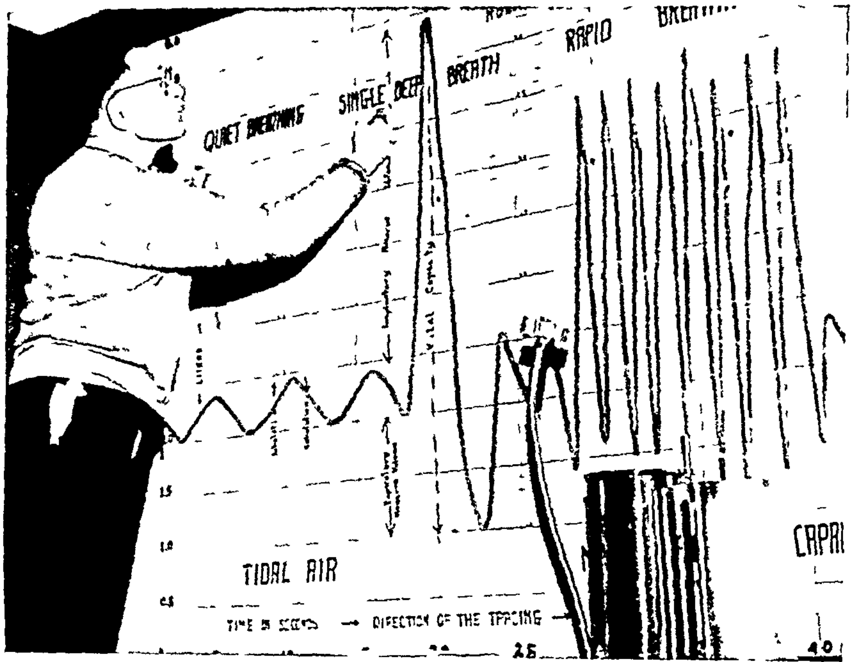
A check for $132,981 from the California Medical Association to the American Medical Education Foundation for the support of the nation's 82 medical schools was presented to Dr. Louis H. Bauer, president of the AMEF, by Dr. Donald A. Charnock (left), president of the California association, and Dr. Dwight H. Murray, A. M. A. President, Napa, Calif., before the House of Delegates.

Above, Dr. Edward M. Gans, desi nated the General Practitioner of tl Year by the House of Delegates durir the Clinical Meeting. The Harlowtoi Mont., physician is approaching th House Speakers' table to receive th gold medal award.



Above, Dr. Arthur M. Olsen, Mayo Clinic, Rochester, Minn., explains his exhibit on esophageal motility in the Civic Auditorium.

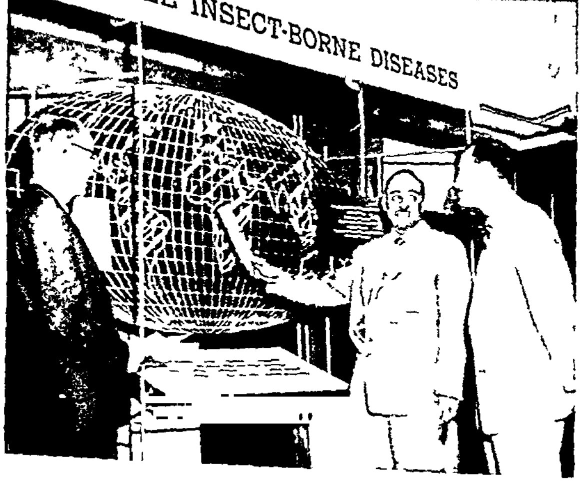
Right, in the Scientific Exhibit, Dr. Everet H. Wood of the Jackson Clinic, Madison, Wis., and the University of Wisconsin Medical School shows a series of x-rays on foreign bodies in the eye to Dr. Emma Dong, Salinas, Calif.



Left, in the Scientific Exhibit, Dr. Edward Matzger of San Francisco was among many physicians who worked over the week end to prepare their exhibits for the opening of the Seattle Clinical Session.

Below, "Fractures about the Elbow" are demonstrated as a special feature of the Scientific Exhibit by Dr. Edmund T. Rumble Jr. (right), Calicoon, N. Y., and Dr. Frederick G. Rosendahl, Minneapolis.

Below, the HEW exhibit, "Importable Insect-Borne Diseases," is explained by Dr. Glenn S. Usher (left) and J. C. Eason Jr. (center) to A. R. Ratcliff, a student at the University of Washington Medical School.



Below, Dr. Sidney Lyttle (left), Flint, Mich., and Dr. Paul Goetowski, Lincoln, Neb., demonstrate the setting of a fracture of the lower end of the radius in the Scientific Exhibit in the Civic Auditorium.

COUNCIL ON MEDICAL SERVICE

A STUDY OF MATERNAL MORTALITY COMMITTEES

This is part 6 of a series of articles by the Committee on Maternal and Child Care of the Council on Medical Service reviewing the organization and operation of maternal mortality study committees. The purpose of this specific study is to obtain information that may be utilized in the preparation of guides that, in turn, may be helpful in the development and operation of maternal mortality committees in other areas of the United States. This article is concerned with the Maternal Welfare Committee of the Wayne County Medical Society. Although this committee's study is an integral part of the total statewide study of maternal deaths in Michigan, the Detroit experience is being described separately because it indicates various differences in technique used on a local level.

Wayne County Maternal Mortality Study

History.—The first Maternal Welfare Committee of the Wayne County Medical Society was established in 1927 and, in cooperation with the Detroit Department of Health, participated in the statewide study of maternal deaths, as mentioned in the history of the Michigan State Study of Maternal Deaths. Again in 1941 a critical study of all maternal deaths in Detroit was started, but because of the war it was interrupted until 1945, when, in conjunction with the Detroit Department of Health, the study was resumed and, with slight variations in procedure, has continued to the present time. This study of maternal deaths is dedicated to the dual purpose of raising the standards of obstetric practice within the county and eliminating the preventable factors contributing to maternal deaths.

Members.—Membership in the Maternal Welfare Committee varies from 25 to 30 members, two-thirds of whom are certified specialists in obstetrics and gynecology; one is a pathologist, one an anesthesiologist, and one an internist. Members are appointed by the president of the Wayne County Medical Society upon the advice of both the outgoing and incoming chairmen. The chairman is appointed by the society president on the advice of the outgoing chairman. Many members are reappointed each year, depending upon the interest they express by attending meetings and their desire to serve. Attempts are made to assure representation on the committee of all hospitals having maternity units.

Scope of Study.—The Maternal Welfare Committee includes in its study the deaths of all women dying during pregnancy or up to six months after termination of the pregnancy. Some of the deaths may be caused by factors indirectly related to the pregnancy and involving associated disease; such deaths are included for the purpose of this study in the calculation of the maternal mortality rate. These nonobstetric deaths are defined as deaths due to disease present before or developing during pregnancy that, though not a direct effect of the pregnancy, was seriously aggravated by the physiological effects of pregnancy and caused the death; for example, deaths caused by heart disease as complicated by pregnancy would be classified nonobstetric. Maternal deaths directly related to pregnancy are classified as due to obstetric causes. An obstetric death is defined as a death due to complications of the pregnancy itself or due to intervention elected or required by the pregnancy or resulting from the chain of events initiated by the complications or the intervention. Included in this group of deaths would be, for instance, those deaths due to amniotic fluid embolism and anesthesia.

All deaths studied are also classified as to preventability and responsibility. The currently significant obstetric problems are thus determined, and the attack upon these problems can be more direct and effective. It is not the purpose of the Maternal Welfare Committee to evaluate the individual physician's competence or to censure his management of a case, but rather its purpose is to emphasize the educational aspects of the cases discussed. The study is designed to be a postgraduate course in the complications of obstetrics. All maternal deaths that occur in Detroit and Wayne County are studied by the committee, but for statistical purposes the ones that are in the nonresident group are reallocated to their county or state of residence.

Operation: Agencies and Personnel Involved.—The Wayne County Maternal Mortality Study has been in continuous operation since its resumption of activities in 1945 at the close of World War II. Since 1950, when the Michigan State Maternal Mortality Study was resumed on a statewide basis, the Wayne County study became an integral part of the total state study. It is a cooperative undertaking of the Wayne County Medical Society, the Michigan State Medical Society, the Michigan Department of Health, and the Detroit Department of Health. As a part of the statewide study, a regional consulting obstetrician (Board certified specialist in obstetrics and gynecology) is assigned to the Detroit area by the state committee. Because the Detroit and Wayne County area has a great many more maternal deaths than does any other area of the state (approximately one-half of the state total), additional obstetricians are appointed jointly by the Wayne County Maternal Welfare Committee and the Michigan Department of Health to assist in the collection of data. The Michigan Department of Health pays these consultants on a case basis as it does the other regional consulting obstetricians throughout the state.

Committee members are W. L. Crawford, M.D., Chairman, Rockford, Ill.; *R. B. Chrisman Jr.*, M.D., Coral Gables, Fla.; Philip S. Barba, M.D., Philadelphia; Harold S. Morgan, M.D., Lincoln, Neb., J. L. Reichert, M.D., Chicago; *Garland* D. Murphy, M.D., El Dorado, Ark.; Howard A. Nelson, M.D., Greenwood, Miss.; and Donald A. Dukelow, M.D., Consultant, Chicago.

The Detroit Department of Health is represented on the Maternal Welfare Committee by its chief of Maternal and Child Health, who also is the secretary of the committee. Stenographic and mimeographing services are provided by the Wayne County Medical Society. The Michigan Society of Obstetricians and Gynecologists has a maternal welfare committee that acts in a liaison capacity between the Michigan State Maternal Mortality Study and the Wayne County Maternal Mortality Study. The two medical schools in the state—the Wayne University College of Medicine in Detroit and the University of Michigan Medical School in Ann Arbor—participate in both the state and Wayne County studies through representatives from their departments of obstetrics and gynecology. The chiefs of both the departments are members of the evaluation subcommittee of the Maternal Health Committee of the Michigan State Medical Society and in that capacity review each maternal death that occurs in Michigan.

The Office of the Division of Maternal and Child Health of the Michigan Department of Health notifies the Wayne County regional consulting obstetrician of a maternal death that has occurred in his area. (All deaths in Wayne County are first reported, of course, to the Detroit Department of Health.) However, before the regional consulting obstetrician makes arrangements for visiting the attending physician and the hospital in which the maternal death occurred, he usually sends to the attending physician a questionnaire or basic information form. The attending physician returns this questionnaire to the regional consulting obstetrician. In this way the latter obtains pertinent preliminary information that facilitates his planning for the collection of data. It also gives the attending physician in the case an opportunity to make a better compilation of his records before the regional consulting obstetrician interviews him. At the interview the consulting obstetrician obtains detailed firsthand information, often personally reviewing the physician's office records of the case. He obtains the autopsy reports and other pertinent information from the hospital records.

After the regional consulting obstetrician obtains all his material and makes a summary of the case and an evaluation of the various facilities and services that the patient had received, he sends this information to the Michigan Department of Health, where all identifying data are removed. A duplicate of the anonymous material is then forwarded to the Wayne County Maternal Welfare Committee. The original is sent to the chairman of the evaluation subcommittee of the Michigan State Medical Society. After receiving his copy, the chairman of the Wayne County committee prepares a uniform protocol of the case. Prior to the meeting at which the case will be discussed, a copy of the protocol is sent to the attending physician, along with an invitation for him to attend. Copies are also sent to all members of the committee and to the obstetric departments of the hospitals in Wayne County. The chairman assigns to various members of the committee the specific task of the opening of the discussion. Prior to the meeting, these persons have studied thoroughly the particular cases to be discussed and generally have acquainted themselves with past and recent literature on the particular complications under study. All medical students, interns, and residents are invited to attend; the time of the meeting is always announced in the *Detroit Medical News*, the weekly news magazine for doctors of medicine published by the Wayne County Medical Society.

At the meeting the discussant, assigned by the chairman, presents the case and gives his analysis as to how he thinks it should be classified. Various points in question are discussed by members of the committee and by anyone else in the audience who wishes to present his views. If the attending physician is present, or if anyone else is familiar with the case personally, he is asked to contribute any additional information that he may have. If the maternal death happens to have occurred at one of the osteopathic hospitals in Detroit, it is treated in the same manner as if it had been in one of the regular medical hospitals. The osteopath in question is sent a basic information form and is visited in the same manner as is a regular physician, but he is not invited to the committee meeting.

As a precautionary measure, a case is not discussed or the protocol sent to the committee members until six months have elapsed from the time of death. Two or three cases are discussed at each meeting; these are held at a regular time each month and last about an hour and a half. An outline form for committee evaluation is appended to the case protocol; the consensus of the committee is obtained as to whether it was a maternal death, whether there were obstetric complications or other associated disease, and, with their judgment being based upon the academic ideal, whether the death was preventable.

It is the opinion of the committee that the factors contributing to maternal deaths must be examined critically and that they must be assessed conscientiously in relation to the best possible standards of medical practice. Their concept of preventability involves three assumptions: (1) that the physician possesses all the knowledge currently available relating to the factors involved in a death; (2) that he has reached a high level of technical ability; and (3) that he has had available to him all the facilities present in a well-organized, properly equipped hospital. The responsibility for death is assigned to the patient, physician, consultant, hospital, or any combination of these. In the discussion of the case the factors that are involved are determined. These are listed and involve one or more of the following categories: (1) prenatal care, (2) technique, (3) no or incompetent consultation, (4) recognition of complications, (5) management of complications, (6) inadequate facilities, and (7) any other factor. The underlying cause of death is determined, if possible, and other contributing causes are listed.

After summarizing the committee's discussion of each case, the secretary includes that information in a letter, the first and last paragraphs of which are of standard form describing the purposes and principal aims of the Maternal Welfare Committee. The letter is so worded that the attending physician who receives it will know that the committee is not criticizing him or censuring him for his management of the particular case. If the case is considered preventable, various recommendations are given, which, if followed in the future on similar cases, would perhaps not result in death of the patient. It is explained that the committee's evaluations are completely without bias and that the identity of the patient, the attending physician, and the hospital are unknown to the committee and those present at the discussion. Further, the committee extends a cordial invitation to the physician to come to any of its meetings and to take part in its discussions if he so wishes.

TABLE 1.—*Live Births, Maternal Deaths and Rates per 10,000 Live Births as Recorded by the Detroit Department of Health and the Maternal Welfare Committee of the Wayne County Medical Society, for the Years 1948-1952**

		Maternal Deaths		Rate/10,000 Live Births	
Yr.	Live Births, No.	Dept. of Health	Committee Study	Dept. of Health	Committee Study
1948	48,197	45	53	9.3	10.9

* From Ott.[1]

Follow-Up.—In addition to the letters sent to the attending and consulting physicians in the case, a summary of the findings is also sent to the administrator of the hospital and the hospital department chief. Each year the Maternal Welfare Committee makes its report to the Wayne County Medical Society; this is printed in the *Detroit Medical News.* The report is a complete account of the number of deaths studied by the committee, with tables showing the causes of death, preventability, and the factors of responsibility. The factors are listed in the order of relative importance in each of the three categories: physician responsibility, patient responsibility, and hospital responsibility. A brief discussion is usually included on the important obstetric hazards that have been brought to the attention of the committee in their study; suggestions are made as to ways and means of lessening those hazards.

A five-year study of maternal deaths in the city of Detroit during the years 1948 through 1952 was presented to the Michigan Society of Obstetricians and Gynecologists at their meeting in February, 1955. These obstetricians and gynecologists devote one of their meetings every other year to discussion of the study made by the Maternal Welfare Committee of the Wayne County Medical Society; one meeting in each alternate year is devoted to a discussion of the statewide study.

TABLE 2.—*Causes of Maternal Deaths, Number and Percentage of Such Deaths and Autopsies Performed, 1948-1952**

	Deaths Studied		Autopsies Performed	
Cause	No.	%	No.	%
Hemorrhage	78	37.9	35	44.8
Cardiovascular	43	20.8	19	44.2
Toxemia	31	15.1	10	32.3

Total	206	100.0	91	44.2
Nonrelated deaths	49	19.2	21	42.8
Total deaths studied	255			

* From Ott.[1]

Brief specific articles regarding various obstetric problems are prepared and published from time to time in the *Detroit Medical News.* The committee has initiated efforts to publicize the need for education of the laity and their part in preventing maternal deaths; it has met with the press in order to provide material for stories on the function and achievements of the committee; programs for radio and television have also been developed.

Material gained from the study by the Maternal Welfare Committee in Detroit has been the source of information used by members of the committee for preparation of papers presented before other state medical meetings. These papers are published in the various state medical society journals and, therefore, afford an opportunity for physicians in other states to become acquainted with what is being done in Michigan and Detroit. These articles have not only been published in state journals but have appeared in such national journals as THE JOURNAL of the American Medical Association and the *American Journal of Obstetrics and Gynecology.*

In order that the program of the Maternal Welfare Committee will be familiar to graduating students of medical schools, the committee conducts occasional meetings or obstetric seminars at the Wayne University College of Medicine. In addition, several hospitals have requested talks by committee members to both their total members and their intern and resident staff on current problems in obstetrics as brought into focus by the committee study.

TABLE 3.—*Distribution of Patients with Obstetric Complication, Associated Disease, and Preventable Factors in the 206 Deaths Classified as Maternal by the Maternal Welfare Committee, 1948-1952**

		Obstetric Complication		Associated Disease		Preventable Factors	
Cause	No.	No.	%	No.	%	No.	%
Hemorrhage	78	78	100	13	16.6	73	93.6
Cardiovascular	43	22	51.2	39	90.7	29	67.2

Total	206	182	88.3	85	41.3	173	84.0

* From Ott.[1]

Results: Statistical Analysis.—Two hundred fifty-five deaths were studied during the five-year period from 1948 to 1952; the Maternal Welfare Committee classified 206 of these as maternal deaths, that is, deaths due to both obstetric and nonobstetric causes, and 49 as deaths caused by nonrelated factors. The Detroit Department of Health, over the same period of time, classified 192 of them as maternal deaths. Table 1 shows the relationship of live births, maternal deaths, and the rate of maternal deaths per 10,000 live births as recorded by both the Detroit Department of Health and the Maternal Welfare Committee of the Wayne County Medical Society. The Detroit Department of Health statistics for the next three-year period (1953-1955) was 4.0 per 10,000 live births (0.4 per 1,000 live births); this is indicative of the progress being made in Detroit. The 206 deaths classified as maternal by the Maternal Welfare Committee were further classified according to cause of death into six categories as indicated in table 2. The percentage rates of these chief causes are given, plus the number and percentage of autopsies performed.

Table 3 further breaks down the six categories of the causes of maternal death into those due to obstetric complications and those due to associated disease; it also gives the number of cases in which preventable factors were found to exist. Table 4 is a detailed analysis of the 206 maternal deaths relative to the number and percentage with preventable factors and major responsibility assignment. It is noted that the major responsibility in 71.9% of these deaths with preventable factors was assigned to the physician; only 9.7% were assigned to the patient and 2.4% to the hospital. Of the 206 deaths that the committee considered maternal, 11.6% were classified as not preventable; preventability factors and responsibility could not be determined by the committee in the remaining 4.4% of the maternal deaths. In regard to the product of the pregnancy in the 206 maternal deaths, analysis indicates 90 live births, 55 fetuses born dead, and 28 fetuses not delivered; 33 cases were due to either ectopic pregnancy or a resultant abortion.

The Maternal Welfare Committee made further detailed analyses of these maternal deaths. The six categories of the causes of maternal deaths were correlated to (1) the method of delivery; (2) various terminations of pregnancy other than regular delivery; and (3) patient factors of preventability, such as the patient's delay in seeking initial care or delay after symptoms and her failure to appear for appointments or to follow the advice of the physician. The largest factor in patient preventability was that of delayed initial care; this accounted for 44.2% of the deaths classified as preventable and the responsibility of the patient. Detailed analyses of the factors causing the maternal deaths that were assigned as the responsibility of the physician indicate that inadequate or improper treatment accounted for 32%; 22.7% were due to complications that the physician failed to recognize; and 19.7% showed poor or no evaluation of hazards. Improper timing of operation, the use of an improper drug or procedure, and failure to seek consultation accounted for the remaining 25.6%. In the deaths considered in some degree to be the responsibility of the hospital, inadequate professional standards was the factor in 26, or 40.6%, of the cases; inadequate facilities in 24, or 37.5%; and inadequate personnel in 14, or 21.9%.

Table 4.—*Maternal Deaths, Preventability and Responsibility, 1948-1952**

		Preventable Factors						Not Preventable		Not Determined	
		Patient		Physician		Hospital					
Cause	No.	No.	%	No.	%	No.	%	No.	%	No.	%
Hemorrhage	78	7	9.0	65	83.3	1	1.3	5	6.4	..	...
Cardiovascular	43	3	7.0	26	60.5	..	...	13	30.2	1	2.3

* From Ott.[1]

Each of the six categories of the causes of maternal deaths was further analyzed as to the detailed cause of death. In the category of hemorrhage, it was found that postpartum uterine atony accounted for 19 deaths, ruptured uterus for 17, and ruptured ectopic pregnancy for 13. Other hemorrhage deaths were due to such causes as abruptio placentae, placenta previa, and laceration of the cervix. In the cardiovascular category, rheumatic heart disease was found to be the cause of 20 deaths, hypertensive cardiovascular disease of 11, vascular pulmonary embolus of 6, and amniotic fluid embolism of 3. In the toxemia category, eclampsia caused 20 deaths, preeclampsia 5, hypertension 5, and chronic nephritis 1. Infection following cesarean section accounted for nine deaths; infection associated with abortion was the specific cause of seven deaths; postpartum (unspecified) infections accounted for four; and infections associated with ectopic pregnancy accounted for three deaths. In the anesthesia category, spinal anesthesia accounted for six deaths, inhalation anesthesia for five, and caudal for one. The miscellaneous causes included electrolyte imbalance in five cases; incompatible blood transfusion in two; hepatitis, air embolism, potassium permanganate poisoning, and chorioepithelioma for one each. This detailed classification of causes of death was further correlated with the major responsibility as assigned to the patient, the physician, or the hospital as well as with whether the preventable factors were undeterminable and whether the death was not preventable.

Table 5.—*Distribution of Maternal Deaths with Regard to Preventability Factors, 1954-1955**

Cause	No.	Preventable	Not Preventable	Not Determined
Hemorrhage	8	6	1	1
Toxemia	8	7	..	1
Cardiovascular	7	3	4	..
Infection	3	2	..	1
Anesthesia	2	1	..	1
Other	3	2	..	1
Total	31	21(67.7%)	5(16.1%)	5(16.1%)

* From Longyear, table, p. 10, with modifications.[2]

The nonrelated, nonobstetric deaths were also analyzed. They included the communicable diseases; infectious diseases; such infections as pyelonephritis; such cardiac diseases as hypertensive and rheumatic heart disease; vascular disease, such as cerebral hemorrhage and thrombosis, that was not considered as the result of pregnancy complications; hemorrhages, such as those from a duodenal ulcer; blood dyscrasias; various malignancies; and others. Even though these nonrelated, nonobstetric deaths were relatively unimportant, the committee did determine preventability factors and assign responsibility in all cases possible. It is interesting to note that in this group of 49 deaths, 37 were classified as not preventable, 7 were classified as preventable with the major responsibility that of the physician, 3 were classified as preventable with the major responsibility that of the patient, and 2 were undeterminable.

Table 6.—*Maternal Deaths, Preventability and Responsibility, 1954-1955**

			Responsibility					
			Patient		Physician		Hospital	
Cause	No.	Preventable	Full	Partial	Full	Partial	Full	Partial
Hemorrhage	8	6		3	1	5		5
Toxemia	8	7		3	1	5		3
Cardiovascular	7	3	1		1	2		2
Infection	3	2	1		1			
Anesthesia	2	1			1			
Other	3	2	2					
Total	31	21	4(12.9%)	6	5(16%)	12		10

* From Longyear, table, p. 10, with modifications.[2]

An analysis of the last three years of the study are in the process of compilation at this time. Tables 5 and 6 represent a partial analysis for the 1954-1955 fiscal year. Of 31 maternal deaths, 21, or 67.7%, were considered preventable, with hemorrhage and toxemia leading the list of causes. The patient was believed fully responsible in 12.9% of the cases and the physician in 16% (table 6). In 38.6% of the preventable deaths, responsibility was assigned partially to physician, patient, and hospital in various combinations. In the deaths assigned either partially or fully to the responsibility of the physician, the factor of greatest incidence was failure on the physician's part to recognize or to evaluate properly evidence of complications; inadequate treatment of complications, failure to obtain consultation, and inappropriate choice of procedure or drug followed as factors of decreasing numerical importance. The committee found that inadequate facilities and lack of accepted professional standards were the preventable factors assigned as the responsibility of the hospital. Delay in obtaining medical care was the most frequent factor in patient responsibility, while failure to follow the instructions of the physician and self-induced abortion or injection of injurious drugs were also factors of importance.

Comments and Conclusions.—Since 1941, except for a three-year interruption during World War II, the Maternal Welfare Committee of the Wayne County Medical Society has conducted a continuous study of maternal deaths in Detroit. Various methods of operation have been tried, and ways and means for making the study as effective as possible have been explored. From time to time, various techniques have been incorporated in the study. In 1949, open committee meetings were inaugurated. All members of the profession, including medical students, interns, and residents, were invited to attend. Because the attending physician did not often respond to a separate letter of invitation to the meeting at which his case was to be discussed, the committee obtained permission from the council of the Wayne County Medical Society to send a letter to each attending physician who has had a case discussed by the committee. This letter contains the detailed findings and recommendations resulting from a complete analysis of the particular case in question. Since 1953, in addition to sending the letter to the attending physician, the committee has been sending a similar letter to the hospital administrator and to the chief of staff of the hospital in which the death occurred. In 1951 the committee developed uniform case protocols, copies of which are sent, before each meeting, to the physicians whose cases are being discussed, to all members of the committee, and to the obstetric departments of the hospitals in Wayne County. In 1951 an internist and a pathologist were added to the committee, and since 1954 the membership has included an anesthesiologist.

Since 1950, an obstetric consultation program has been sponsored by the committee. This is a volunteer program, with specialists on the committee agreeing to serve. Consultation is given without fee for indigent cases in hospitals not having obstetric specialists on their medical staff. In addition, the Detroit Department of Health, in cooperation with the committee, has established prenatal lectures as well as clinic service for patients of the lower economic groups who are often not hospitalized. Effective dissemination of specialized information to the busy practitioner has always been a problem. In an effort to help alleviate this, the committee is promoting the publication of articles designed to present recent advances in obstetrics. These frequently appear in the weekly *Detroit Medical News.*

Through the medium of its open meetings, the committee has endeavored to have cases presented over certain periods of time that would emphasize the varied aspects of recurrent complications encountered in its study. By a concentration of discussions on certain problems and complications that occur frequently, the committee has been able to establish mutually acceptable standards of management of such cases. Also, when cases of maternal death are reviewed that illustrate relatively rare problems, the committee has endeavored to obtain discussions on these particular problems by physicians who have particular interest in, or information on, these complications. In these and other ways, the committee is always planning for more proficiency and effectiveness in its study of maternal deaths.

Recently, the Maternal Welfare Committee has recommended that a subcommittee or board of review be established to examine all case material available, determine those cases that are most suitable for discussion, and, in cases where information is not complete, request such additional data as the board of review feels is necessary. In this way, then, it is anticipated that the committee study will contribute more valuable data to the current postgraduate educational program. The proposed board or subcommittee would also review and classify at interim meetings all cases that are not presented for review at the regular monthly open meetings.

In conclusion, the philosophy of the Wayne County experience can be summed up in two quotations by a former chairman of the Maternal Welfare Committee. He points out that "Critical reviews of maternal deaths have become essential in determining what are the current problems in obstetric practice. Their evaluation is necessary to discover our professional shortcomings."[3] He states in his committee report for 1953-1954 that "Preventability and responsibility of the maternal deaths studied are designated as a means of determining areas of currently significant obstetrical problems for which effective solutions are needed. . . . It is the conviction of the Committee that only by honestly recognizing the existing problems and by sincerely attempting to find satisfactory answers can true professional progress be maintained."[4]

MEDICAL NEWS

ARIZONA

Cancer Seminar in Phoenix.—The American Cancer society, Arizona division, will hold its 1957 cancer seminar, Jan. 10-12, 1957, at the Paradise Inn in Phoenix. Dr. Edward H. Bregman, Phoenix, president of the division, will serve as chairman and Dr. James D. Barger, Phoenix, as co-chairman. Credit for attendance will be given by the Academy of General Practice. Out-of-state speakers will include Drs. Joseph W. Gale and John Z. Bowers, Madison, Wis.; Leo H. Garland and David A. Wood, president, American Cancer Society, San Francisco; David C. Dahlin, Rochester, Minn.; J. Vernon Luck, Los Angeles; Eugene P. Pendergrass, Philadelphia; Hans G. Schlumberger, Columbus, Ohio; Dominic A. DeSanto, San Diego, Calif.; Joe V. Meigs, Boston; and Alfred A. Gellhorn, New York. For registration, write to Arizona Division, American Cancer Society, 1429 N. 1st St., Phoenix.

ILLINOIS

Personal.—Col. Roland I. Pritikin, M. C., U. S. Army Reserve, Rockford, recently returned from the International Congress of the History of Science, Florence, Italy, where he spoke on "History of Treatment of Congenital and Hereditary Eye Defects" and "History of the Introduction to the Management of Mass Eye Casualties Resulting from Radiation Trauma."

Chicago

Lectures on the Growth of Medicine.—Northwestern University Medical School will present the 1957 lectures in "The Growth of Medicine," Tuesdays, 5-6 p. m., in room 641 of the Ward Memorial Bldg., 303 E. Chicago Ave. The January schedule includes the following lectures:

Jan. 8, Barry J. Anson, Ph.D., professor of anatomy, The Debt of Medicine to Ancient Greece and Rome.
Jan. 15, Frederick Stenn, associate professor of medicine, The Medicine of Primitive and Ancient Man.
Jan. 22, Raymond W. McNealy, associate professor of surgery, emeritus, The Influence of the Cook County Hospital on Medical Education in the United States.
Jan. 29, Benjamin Boshes, professor of nervous diseases, The Development of Our Knowledge of Psychiatry.

Lectures on History of Surgery.—On Tuesday, Jan. 8, 1957, at 8 p. m. the International College of Surgeons will present "Early French Surgery" by Dr. G. Kasten Tallmadge, professor of the history of medicine, Marquette University School of Medicine, Milwaukee. All physicians are welcome to attend the lecture, which will be given at the Surgeons' Hall of Fame, 1524 Lake Shore Dr.

Course in Radiation Physics.—The annual course in radiation physics and the James T. Case Lectures for residents in radiology at the hospitals associated with Northwestern University Medical School will be open to all interested physicians (Monday and Thursday, 6:45-9 p. m., Jan. 7–May 7, 1957, in the Morton Research Building, 303 Chicago Ave.). For further information write to the Director, Graduate Division, Northwestern University Medical School, 303 E. Chicago Ave., Chicago 11.

University News.—Dr. William M. S. Ironside of the Royal Infirmary, Edinburgh, Scotland, has been appointed assistant professor of otolaryngology in the department of surgery at the University of Chicago School of Medicine. Dr. Ironside served as a fellow and instructor in otolaryngology at the university for the year ending July 31, 1955. Mrs. Ironside is also a physician.——Dr. John F. Kramer, formerly on the faculty of the Yale University School of Medicine, New Haven, Conn., has been named associate professor of psychiatry at the University of Chicago School of Medicine. Dr. Kramer has been affiliated with Children's Hospital, Los Angeles; the Alfred I. Dupont Institute, Wilmington, Del.; Child Development Institute, New York Hospital; and the Rochester (N. Y.) Child Health Institute.——Dr. William A. J. Crane, lecturer in pathology at the University of Glasgow, Scotland, has joined the staff of the Ben May Laboratory of Cancer Research at the University of Chicago School of Medicine. Dr. Crane is a member of the Scottish Society of Experimental Medicine, the Pathological Society of Great Britain and Ireland, the Royal Medical Society of Glasgow, and the British Medical Association.——Dr. John T. Grayhack has been named director of a new laboratory for research in urology at Northwestern University Medical School. The laboratory was made possible by the Lucy and Edwin Kretschmer Fund, created in honor of his wife and son by the late Dr. Herman L. Kretschmer, a past-president and treasurer of the American Medical Association and a Northwestern alumnus, who died in 1951.——Northwestern University Medical School announces the appointment of Dr. Zachary Felsher, formerly on the faculties of the University of Chicago and the University of Illinois, as assistant professor in dermatology; Dr. Frank J. Fara, chief of obstetrics and gynecology at St. Anthony de Padua Hospital in Chicago and at MacNeal Memorial Hospital in Berwyn, as assistant professor in obstetrics and gynecology; and Dr. Harold Koenig, chief, department of neurology, Veterans Administration Research Hospital at the Northwestern Medical Center, as assistant professor in neurology and psychiatry.——Dr. Chi Kong Liu has been promoted to clinical associate in medicine at Chicago Medical School. Dr. Liu, a native of Canton, China, received his medical degree at National Central University in Nanking, completed his internship and residency in China, and entered Stanford University School of Medicine, Stanford University—San Francisco, for postgraduate studies, serving as a fellow in medicine and a fellow in cardiology. Dr. Liu is co-author of a new book on cardiac pressures and pulses with Dr. Aldo A. Luisada, head of the department of cardiology at Chicago Medical School.

MASSACHUSETTS

Meeting on Gastroenterology.—The Boston Gastroenterological Society (Dr. John J. Byrne, president) will hold a dinner meeting for members and guests, Jan. 9, 1957, 6:30 p. m. "Diseases of the Pancreas" will be the subject of a panel discussion in which "Cancer of the Pancreas" will be presented by Dr. Charles G. Child III, professor of surgery, Tufts College Medical School; "Acute Pancreatitis" by Dr. Perry J. Culver, associate in medicine, Harvard Medical School; "Laboratory Aids in the Diagnosis of Pancreatic Disease" by Dr. Franz J. Ingelfinger, associate professor of medicine, Boston University School of Medicine; and "Surgery of the Sequelae of Pancreatitis" by Dr. Kenneth W. Warren, department of surgery, Lahey Clinic.

MISSOURI

Hanau Loeb Lecture.—The Alpha Pi chapter of Phi Delta Epsilon fraternity at the St. Louis University School of Medicine will hold its 12th annual Hanau W. Loeb Lectureship Jan. 8, 1957, at 5 p. m. The guest speaker, Dr. Shields Warren, Harvard Medical School, Boston, will discuss "Man and His Atomic Environment." Dr. Warren is the former director of the division of biology and medicine, U. S. Atomic Energy Commission.

NEW YORK

Society News.—At a meeting of the Westchester chapter, American Federation for Clinical Research, Nov. 15, at the Nurses' Auditorium, White Plains Hospital, Dr. Charles Weller Jr., Larchmont, presented "The Oral Anti-Diabetic Compounds" and Drs. John J. Kneisel, White Plains, and O. Alan Rose, New York City, presented "Two Cases of Diencephalic Syndrome, One Treated with Splanchnicectomy and One with Reserpine."

Pilot Project in Mental Hygiene Institutions.—A program to increase volunteer services in the state's mental hygiene institutions was inaugurated in August with the appointment of a statewide director of volunteers, Miss Barbara Griffiths, former director of volunteers at Hudson River State Hospital. According

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

to Dr. Paul H. Hoch, commissioner of mental hygiene, the effect of a volunteer program on hospital-community relationships was successfully proved in the experimental project at the Hudson River State Hospital. As a first step in the new program, Miss Griffiths will survey the needs and the ability to meet these needs in each of the state's 27 institutions and the community it serves. The expanded volunteer program is being initiated under a grant obtained from the Doris Duke Foundation, New York City, by the New York State Society for Mental Health.

Hospital News.—Grants of $256,400 for research and nonoperating purposes at Hillside Hospital, Glen Oaks, L. I., were recently announced by Dr. Joseph S. A. Miller, medical director. Hillside is a nonprofit mental hospital affiliated with the Federation of Jewish Philanthropies.——The Salvation Army announces the appointment of Drs. Samuel D. Blum, New York City, and Ancel U. Blaustein, Hollis, L. I., to the staff of the new Booth Memorial Hospital in Queens. Dr. Blum is a clinical professor and Dr. Blaustein is assistant professor of pathology at the New York Medical College, Flower and Fifth Avenue Hospitals. Booth Memorial Hospital (North Hempstead Turnpike and Main Street, Flushing) was scheduled to be completed in December. The 200-bed institution will provide general care for middle-income families, facilities for the study of geriatrics, and the continuation of the program for unmarried mothers.

University News.—Dr. Kwang Soo Lee, associate professor of pharmacology, Jefferson Medical College of Philadelphia, has been appointed associate professor of pharmacology at the State University of New York College of Medicine at New York City, Brooklyn. Dr. Lee holds the degrees of M.D. and Ph.D. in pharmacology from Keijo Imperial University, Japan, and of Ph.D. in biochemistry from Johns Hopkins University, Baltimore.——Albany Medical College announces the formation of a department of microbiology, an outgrowth of the departments of bacteriology and pathology. Scott V. Covert, Ph.D., has been named professor and chairman of the new department, which will have the primary duty of conducting microscopic studies of bacteria, viruses, fungi, and parasites in relation to infectious diseases. His staff will also assist in the training of medical technologists at Albany Hospital and in the teaching of nurses at the Albany Medical Center School of Nursing.——Dr. Douglass S. Thompson, clinical instructor in medicine at New York University College of Medicine, was named university physician, to succeed Dr. John E. Sawhill, who retired after 32 years of service. Dr. Thompson has served as New York University intern and resident at Bellevue Hospital and, since 1953, as an assistant in medicine at the college of medicine. For the last two years he also has been a U. S. Public Health Service trainee at Bellevue. Dr. Thompson is secretary of subsidiary board A of the National Board of Medical Examiners, New York City, and a member of the research committee of the American College Health Association.

New York City

Dr. Graef Honored.—Dr. Irving P. Graef, who has been a leader in the work of the National Committee for Resettlement of Foreign Physicians (31 Union Sq. W.) since its organization in 1939, was honored Nov. 5 as the retiring chairman of the board of directors "for his distinguished efforts in helping foreign physicians reestablish themselves in their profession in the United States." He was presented with a bronze plaque and two volumes of letters of appreciation at a luncheon in his honor at the New York Academy of Medicine. Dr. Graef will remain national vice-chairman of the committee. Dr. Robert Boggs, former dean of the New York University Post-Graduate Medical School, is the new chairman of the board. Dr. Graef has served as secretary-treasurer of the Society of Experimental Biology and is associate editor of *Diabetes——The Journal of the American Diabetes Association*. He is a member of the board of directors of National Medical Fellowships, which provide money for Negro medical students for postgraduate study in medical schools.

Personal.—Dr. Abraham Kardiner, clinical professor of psychiatry, Columbia University College of Physicians and Surgeons, recently addressed the Long Island Psychiatric Society at its meeting at the Veterans Administration Hospital, Northport, on "Social Conditions Under Which Psychiatry Arose and Can Survive."——Dr. Maurice L. Tainter, director of the Sterling-Winthrop Research Institute in Rensselaer, has been elected a trustee of Albany Medical College. He is a past-president of the New York Academy of Sciences, and formerly was head, department of physiological sciences, Stanford University in California.——Dr. Maxwell L. Littman, research associate, department of microbiology, Mount Sinai Hospital, was elected chairman of the division of mycology of the New York Academy of Sciences for the 1957 term. He is co-author of "Cryptococcosis-Torulosis" with Dr. Lorenz E. Zimmerman of the Armed Forces Institute of Pathology, Washington, D. C.——Dr. Francis S. Caliva, assistant professor of medicine, State University of New York College of Medicine, Syracuse, has been appointed medical director of the Syracuse Dispensary, 601 E. Fayette St., succeeding Dr. Richardson K. Noback, who resigned to become affiliated with the University of Kentucky College of Medicine, Louisville.——Dr. Bernard Kalfayan has been appointed director of laboratories at the Roosevelt Hospital. Born in Turkey and now a naturalized American citizen, Dr. Kalfayan was graduated from the American University of Beirut, School of Medicine, Lebanon. He has served as assistant professor of pathology at Cornell University Medical College, associate attending pathologist at New York Hospital, associate pathologist at Roosevelt Hospital, and director of laboratories of Beekman-Downtown Hospital.

OREGON

Personal.—Dr. Howard P. Lewis, professor of medicine, University of Oregon Medical School, Portland, has been appointed to the National Advisory Heart Council, according to an announcement by the surgeon general of the Public Health Service.

Professor of Obstetrics and Gynecology.—Dr. Ralph C. Benson, San Francisco, has been appointed as professor and as the first full-time head of the department of obstetrics and gynecology at the University of Oregon Medical School, Portland. Dr Benson previously served as associate professor of obstetrics and gynecology at the University of California Medical School, San Francisco. Dr. Howard C. Stearns, Portland, who has been a faculty member since 1932 and clinical professor and head of the department since 1945, will continue as clinical professor and will assume the post of senior consultant.

TENNESSEE

Course on Diseases of the Chest.—A course on diseases of the chest will be sponsored by the council on postgraduate medical education of the American College of Chest Physicians with the cooperation of the southern chapter of the college and the Vanderbilt University School of Medicine, Nashville, at the school of medicine, Jan. 14-19, 1957. The tuition fee, $75, includes five luncheons. Out-of-state participants will include Drs J. Winthrop Peabody, Washington, D. C., Gerritt W. H. Schepers, Saranac Lake, N. Y.; M. Jay Flipse, Miami, Fla.; Alvis E Greer, Houston, Texas; Osler A. Abbott, Emory University, Ga., Lawrence H. Strug, New Orleans, John S. Harter, Louisville, Ky.; and Robert P. Glover, Philadelphia. Forty-two hours of informal credit will be allowed by the Academy of General Practice. Applications may be sent to the American College of Chest Physicians, 112 E. Chestnut St., Chicago 11.

WASHINGTON

Professor of Pediatrics.—Dr. Robert A. Aldrich, associate professor of pediatrics at the University of Oregon Medical School, Portland, has been appointed by the University of Washington School of Medicine, Seattle, as head of the department of pediatrics. Dr. Aldrich previously served as a resident for three years at the University of Minnesota Hospital, Minneapolis, and an associate and consultant in pediatrics at the Mayo Clinic, Rochester, Minn. He succeeds Dr. Walter B. Seelye, who has been forced to limit his activity because of illness.

Health Officers Needed.—The Washington State Personnel Board (212 General Administration Bldg., Olympia) announces that applications will be accepted until further notice for (1) district health officer (salary, $864 to $1,032) and (2) medical health officer (salary, $692 to $826). Applicants must be graduates of an approved school of medicine, including or supplemented by a one-year rotating internship. In addition, district health officer applicants must have completed one year of graduate training in public health and must have had (1) at least two years of successful full-time experience in public health work; or (2) approved public health residency training, which may be substituted year for year for the required experience; or (3) three years of successful, full-time, professional medical practice. A license to practice medicine in the state of Washington must be acquired before probationary appointment or at the first meeting of the board of medical examiners after such appointment. Residence in the state is not required before appointment. A recent photograph should accompany application.

WEST VIRGINIA

Cancer Registry.—A central cancer registry, under the joint sponsorship of the state department of health and the West Virginia Cancer Society, will be available on and after Jan. 1, 1957. The registry will be housed with the state department of health, and the personnel will be associated closely with the divisions of cancer control and vital statistics. The central registry, which initially will have the cooperation of at least 11 hospitals, will provide a systematic follow-up of all cancer patients and keep them under adequate lifetime medical observation.

GENERAL

Course on Radiologic Safety.—A full-time course in radiologic safety will be given Jan. 7-18, 1957, by the New York University Post-Graduate Medical School in cooperation with the U. S. Atomic Energy Commission. The course is designed for physicians, engineers, and persons in research laboratories. For the convenience of those who cannot take the course full time, it will be repeated on a part-time basis from Jan. 30 to May 22. There will also be an optional laboratory session from Jan. 21 to Feb. 1. For information, write to the Dean, Post-Graduate Medical School, 550 First Ave., New York 16.

Seminars on Thyroid-Uptake Measurement.—The medical division of the Oak Ridge (Tenn.) Institute of Nuclear Studies will present six thyroid-uptake seminars this winter and spring, to provide instruction in a standard method of calibrating the uptake of radioiodine by the thyroid. Seminars A and B (Jan. 14-15 and Feb. 11-12, 1957) will be limited to participants in the Oak Ridge survey of thyroid-uptake measurement. Seminars 1 and 2 (March 18-19 and April 15-16) will be open to a limited number of qualified physicians and physicists who have not participated in the institute's thyroid-uptake calibration survey. The fee will be $25. Seminar 3 (May 17) will be open only to representatives of manufacturers of thyroid-uptake equipment. A maximum of 60 participants will be accepted, and a $25 fee will be charged. Seminar 4 (June 10-14) will accommodate a total of 30 technicians employed under the direction of physicians who have attended one of the previous seminars. This experimental seminar will train technical assistants for work with professional staff members. A fee of $25 per person will be charged. Information concerning any of the seminars, and application forms may be obtained by writing Mr. William Busby, Oak Ridge Institute of Nuclear Studies, Medical Division, P. O. Box 117, Oak Ridge, Tenn.

Industrial Accidents Decrease.—The National Safety Council (425 N. Michigan Ave., Chicago 11) reports that industrial injury rates for 1955 showed a reduction in frequency and an increase in severity compared with those of 1954. Of the 40 basic industry classifications, 25 reduced their frequency rates. Although more than half reduced their severity, this reduction did not make up for the increases of others. The average accident-frequency rate for employees in all industries submitting company reports to the council, based on the number of disabling injuries per million man-hours, was 6.96 in 1955, a reduction of 4% from the year before. This is the first time that the all-industry rate has been held to less than 7. The lowest employee frequency rate (0.86) was reported by the communications industry. This was a 34% improvement from the 1954 rate, which was also the lowest for all industries. Electrical equipment held second place with a rate of 2.13, a 15% reduction. Aircraft manufacturing and cement made 21% improvements. The average accident severity rate for all industries reporting to the council, based on the number of days lost per million man-hours, was 815 last year—an increase of 2%. Tobacco, with a rate of 87 and a 1955 reduction of 59%, was first in the severity column; communications was second, with a rate of 97; and service industries third, with a rate of 105.

Foundation for Eye Care.—The National Medical Foundation for Eye Care, a nonprofit scientific and educational institution, has been incorporated in New Jersey, "to provide American ophthalmology with an agency to present to the public generally and to fellow physicians pertinent information on the care and treatment of the eyes." Dr. Ralph O. Rychener, Memphis, Tenn., is president of the foundation; Dr. Edwin F. Tait, Norristown, Pa., vice-president; and Dr. Charles E. Jaeckle, East Orange, N. J., secretary-treasurer. Other members of the board of trustees are Drs. Alson E. Braley, Iowa City; Frederick C. Cordes, San Francisco; Paul A. Chandler, Boston; J. Spencer Dryden, Washington, D. C.; Harold F. Falls, Ann Arbor, Mich.; Everett L. Goar, Houston, Texas; Erling W. Hansen, Minneapolis; Albert D. Ruedemann, Detroit; Barnet R. Sakler, Cincinnati; and Derrick T. Vail, Chicago. The foundation invites all ophthalmologists and other physicians in eye care to become charter members. Applications are available through Dr. Charles E. Jaeckle, secretary-treasurer, at 136 Evergreen Pl., East Orange, N. J. The foundation will establish an administrative office in New York City about Jan. 1, 1957, and will also make available an affiliate membership for persons other than doctors of medicine who are interested in aiding the purposes of the foundation.

Society News.—Newly elected officers of the American Association of Neuropathologists include: Dr. Ben W. Lichtenstein, Chicago, president; Dr. Konstantin Scharenberg, Ann Arbor, Mich., vice-president; and Dr. Leon Roizin, New York, secretary-treasurer.——Newly elected officers of the New England Roentgen Ray Society include: Dr. Leslie K. Sycamore, Hanover, N. H., president; Dr. Harvey R. Morrison, Boston, vice-president; Dr. Raymond A. Dillon, Winchester, secretary; and Dr. Magnus I. Smedal, Boston, treasurer.——Officers of the Medical Library Association include Miss Bertha B. Hallam, Portland, Ore., president; Mrs. Henrietta T. Perkins, New Haven, Conn., secretary; Miss Pauline Duffield, Austin, Texas, treasurer; and Mr. Thomas E. Keys, Rochester, Minn., president-elect.——The American Board of Legal Medicine recently elected the following officers: Dr. Alfred Koerner, New York City, president; Dr. Harold Lefkoe, Philadelphia, vice-president; Dr. Sidney I. Franklin, Youngstown, Ohio, second vice-president; Dr. Harold M. Pritchard, Niles, Mich., third vice-president; Dr. Maxwell M. Booxbaum, Bronxville, N. Y., secretary; Dr. Louis J. Gelber, Rockville Centre, N. Y., assistant secretary; Dr. Israel Bernard Malkin, Brooklyn, N. Y., treasurer; and Dr. Ewing H. Crawfis, Little Rock, Ark., assistant treasurer. The board's 1957 convention will be held in New York City immediately preceding the A. M. A. convention.

Fund for Psychiatry.—The American Fund for Psychiatry (organized in 1954) announces fellowship awards for 1956, totaling $30,000, to the following medical schools and other training institutions to support teaching appointments of these young physicians:

John A. MacLeod, department of psychiatry of the University of Cincinnati College of Medicine, second year grant.
Virgilio G. Santiago, Hahnemann Medical College and Hospital of Philadelphia.
Francis H. Hoffman, Temple University School of Medicine, Philadelphia, second year grant.
Bernard P. Ottenberg, University of Pennsylvania School of Medicine, Philadelphia.
Thomas S. Szasz, Institute for Psychoanalysis, Chicago.

The fund raises money from corporations, foundations, and individuals for the purpose of financing academic and research appointments in psychiatry. Its aim is to reduce the critical shortage of teachers and researchers in the mental health field. The awards were made by a committee of physicians under the chairmanship of Dr. Vernon W. Lippard, dean of the Yale University School of Medicine, New Haven, Conn. In the two years of its existence the fund has made specific grants and fellowship awards in support of psychiatric research and training totaling $75,000. It is currently engaged in a campaign to raise $250,000 for 1956 to finance future research grants and fellowships.

Outbreaks of Encephalitis.—In its communicable disease summary for the week ended Sept. 22, the National Office of Vital Statistics of the U. S. Public Health Service says that Dr. Roy F. Feemster, Massachusetts Department of Public Health, Boston, has reported another suspected human case of eastern equine encephalitis that proved to be fatal. The total for the year is now 12 affected persons, of whom 7 have died. Virus has been isolated in four fatal cases, and serologic evidence of infection has been found in three of the survivors. A total of 38 cases in horses has been reported, from which 6 virus isolations have been made, and a high antibody titer was found in one surviving animal. Two virus isolations have been made from pheasants on pheasant farms. A recent confirmed case in a horse was found in Southbridge near the Connecticut border. Infection in pheasants on farms, confirmed by virus isolation, has been found in nearby areas of Connecticut.

In other areas, human cases of arthropod-borne types of encephalitis have been found as follows: three suspected human cases of eastern equine infection in New Jersey and two in Louisiana are being investigated. Serological evidence of St. Louis encephalitis has been found in one case in California and one in Colorado. There are 12 cases in Colorado in which the presumptive diagnosis is of the St. Louis type of infection. California has reported eight cases of western equine encephalitis for which there is serologic evidence of infection. Of 850 pools of mosquitoes received for testing in this state, western equine virus has been isolated from 124; tests on 372 have revealed negative results, and the remainder are still being tested. A few cases of encephalitis are being investigated in western Kansas, not far from an area in Texas where cases are also reported to be occurring. Eight suspect cases, with one death, from western equine encephalitis reported in the state of Washington in July, were still under investigation. Two cases with one death had occurred in Idaho, but neither had been confirmed.

Mine Workers Welfare and Retirement Fund.—The annual report of the United Mine Workers of America Welfare and Retirement Fund, released Sept. 6, highlights the 10th anniversary of the fund's operations. Benefits paid during this decade totaled $880,819,489.10 and aided 972,004 beneficiaries—miners, their families, their widows and orphans. Revenues received during the 10-year period totaled $1,036,650,955.03. The fund is organized and administered as a separate entity, independent of the union and the coal operators, by its three trustees, John L. Lewis, chairman and chief executive officer, Charles A. Owen, and Josephine Roche.

The annual report shows that on June 30, 1956, there were 61,546 retired miners receiving the $100 monthly pensions, in addition to federal Social Security or other income the miner may enjoy. The average age of these pensioned miners at retirement was 63.8, and they had worked an average of 32.3 years in the coal industry. The annual report further shows that funeral expenses and widows' and survivors' benefits of $3,190,358.94 aided 7,320 widows, orphans, and other survivors of deceased miners. Additional payments of $69,807 in mine disaster benefits aided the families of 241 miners killed or seriously injured in mine disasters during the year.

A major development during the past fiscal year in the medical and hospital program, under the direction of Dr. Warren F. Draper, Washington, D. C., executive medical officer of the fund, was the opening of a network of 10 hospitals operated by the Miners Memorial Hospital Association (see The Journal, March 27, 1954, pages 1101-1103). The fund's unexpended balance as of June 30, 1956, was $130,172,370.58, an increase of more than 26 million dollars over the previous fiscal year. The total revenues for the year were $154,227,174.35, the total expenditures were $127,662,715.10, of which 97.1% were payments aiding 206,919 beneficiaries. All administrative costs of the fund, including those of its Washington headquarters and its 10 area medical offices, were 2.9% of the total fund expenditures.

FOREIGN

Personal.—Sir Russell W. E. Brain, Bt., president of the Royal College of Physicians, has accepted appointment as a trustee of the Ciba Foundation, an organization dedicated to the promotion of international cooperation in medical and chemical research.

Postgraduate Courses in Austria and Switzerland.—The West German Federation of Physicians' Councils has scheduled a continuation school for medical practitioners, at which the general subject will be "Sulfonamide, Antibiotica and Cortisone." Parallel courses will be given March 11-23, 1957, at Bad Gastein, Austria, and at Davos, Switzerland. The official language of the conventions will be German. Information may be obtained from Wolfgang Brune at the federation's headquarters, Haedenkampstrasse 1, Koln-Lindenthal, Germany.

Training Program in Urology.—The first training program in Urology to be given in India will be set up by Dr. Roger W. Barnes, chairman of the department of urology at the College of Medical Evangelists, Loma Linda, Los Angeles, who left July 1 for Vellore, India, where he will remain until next summer. The program will be established at the Christian Medical College, where Dr. Barnes will also lecture in urology under a Fulbright award.

EXAMINATIONS AND LICENSURE

American Board of Anesthesiology. *Part I.* Various locations, July 19 Final date for filing application is Jan. 19. *Oral* Asheville, No Car, Mar 24-29. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn

American Board of Dermatology. *Written.* Several cities, June 27 *Oral.* Baltimore, Oct. 11-13. Sec., Dr. Beatrice Maher Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *Written* Oct. 21. *Oral* New Orleans, Feb. 4-8; Boston, April 3-6. Final date for filing application is Jan. 2. Chicago, May 27-29, San Francisco or Los Angeles, September Final date for filing application is Feb 1. *Subspecialties Gastroenterology* Philadelphia, April 5-6. Final date for filing application is March 1 Exec Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology. *Part I* Various cities of the United States, Canada, and military centers outside the Continental United States, Feb. 1. Candidates must submit case reports to the office of the Secretary within thirty days of being notified of their eligibility to Part I. The cases must be *prepared in the manner* described in the Bulletin of the board with a duplicate index list. *Part II.* Chicago, May 16-25 Request for reexamination in Part II must be received prior to Feb 1 Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio

American Board of Ophthalmology· *Written.* Jan 21. Final date for *filing application* was July 1. *Oral* New York, May 23-27, Chicago Oct. 7-11. *Sec.*, Dr. Merrill J. King, Box 236, Cape Cottage Branch *Portland* 9, Maine.

American Board of Orthopaedic Surgery. *Oral Part II* Chicago, January 1957. Final date for filing application was Aug. 15 Sec, Dr Sam W. Banks, 116 South Michigan Ave, Chicago 3.

American Board of Otolaryngology. Chicago, Oct 7-11. Final date for filing application is April. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology. *Oral and Written Pathologic Anatomy and Clinical Pathology* Washington, April 4-6. Final date for filing application is March 1. Sec., Dr. Edward B. Smith, 1040 West Michigan St, Indianapolis 5

American Board of Physical Medicine and Rehabilitation *Parts I and II.* New York City, June 8-9. Final date for filing application is March 1. Sec., Dr. Earl C. Elkins, 200 First St., S W., *Rochester*, Minn

American Board of Plastic Surgery. *Entire Examination* Philadelphia, May 4-6. Final date for filing case reports is Jan 1 Corres Sec, Mrs Estelle E. Hillerich, 4647 Pershing Ave, St. Louis 8

American Board of Preventive Medicine. *Oral and Written Public Health.* Schools of Public Health, April 11-13. *Aviation Medicine* Denver, May 9-11. *Occupational Medicine St. Louis, April* 26-28 Sec, Dr Thomas F. Whayne, 615 North Wolfe St., Baltimore

American Board of Proctology. *Oral and Written Parts I and II* September. Sec., Dr. Stuart T. Ross, 520 Franklin Ave, Garden City, N. Y.

American Board of Psychiatry and Neurology *Oral* New Orleans, Mar. 18-19. Final date for filing application was Sept. 10. Sec, Dr David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn

American Board of Radiology. Tampa, April 1-6 Final date for filing application is Jan. 1. Washington, Sept. 23-28 Final date for filing application is June 1. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg, *Rochester*, Minn

American Board of Surgery: *Part II.* Los Angeles, Jan. 14-15, San Francisco, Jan. 17-18, Houston, Feb. 18-19, Nashville, Mar 11-12, Boston, April 8-9, and New York, June 10-11.

American Board of Urology: February 1957. Sec, Dr William Niles Wishard, 1711 N. Capital Ave, *Indianapolis* 7.

Board of Thoracic Surgery: *Written* Various centers throughout the country, February 1957, and the closing *date for* registration is *Dec* 1, 1956. Sec., Dr. William M. Tuttle, 1151 *Taylor Ave*, Detroit 2

GOVERNMENT SERVICES

AIR FORCE

Air Force to Build Medical Center.—The Air Force has announced that the new 8-million-dollar Aero Medical Center, to be built at Brooks Air Force Base, San Antonio, Texas, will house the School of Aviation Medicine, which has been dividing its operations between Randolph Air Force Base, Texas, and Gunter Air Force Base, Alabama. The center, which is scheduled for completion by the end of 1958, was originally authorized by the 82nd Congress in the fiscal year 1953 military construction program.

The first construction contracts provide for an academic building, a flight medicine laboratory, research laboratory shops, and supporting utilities. Contracts to be awarded for the remainder of the facilities include an altitude building and a research building. Establishment of this aeromedical center will allow the Air Force to conduct more extensive research into the medical aspects of supersonic flight problems and to provide greater aviation medicine teaching facilities than are now available. Emphasis will be placed on developing means of protecting fliers at the high speeds and altitudes that are now encountered or that are expected to be encountered in the future.

Noise Exposure Program.—The U. S. Air Force announces that a hazardous noise exposure program is being established to provide an audiometric examination as a part of the routine physical examination of all military and civilian personnel who enter or terminate service in the Air Force. The provision of this examination, which has already begun at Lackland Air Force Base, Texas, is intended to supply a base line for determining and controlling the effects of exposure to hazardous noise. This Air Force program represents the first step of such broad scope in the study, control, and reduction of hearing damage produced by noise.

Joint Committee on Aviation Pathology.—The Joint Committee on Aviation Pathology established by the Department of Defense, Nov. 14, 1955, held its second scientific session at the Armed Forces Institute of Pathology Nov. 15-16, 1956. This committee consists of representatives of the U. S. Air Force, Army, and Navy, the British Royal Air Force and Navy; the Royal Canadian Air Force, and the Armed Forces Institute of Pathology. Its objectives are to study the pathological reports of fatal aircraft accidents in order to evaluate their possible cause; to observe recurring traumatic lesions that may be preventable; to determine the significance of preexisting subclinical lesions in aircrew personnel; to investigate the possible insidious changes induced by repeated exposure to flight conditions; and to establish a long-range program of collection of such information and rapid dissemination of it to the member services.

The second scientific session was attended by 100 civilian and military personnel, before whom about 20 papers were presented. Col. Frank M. Townsend, M. C., U. S. A. F., was elected chairman of the committee for the coming year, replacing Wing Commander E. Bruce Harvey, R. A. F., who had served as chairman since the committee was established.

New Two-Star General.—Brig. Gen. Olin F. McIlnay has been promoted to the rank of major general by direction of the President. General McIlnay was commissioned a first lieutenant in the Medical Reserve in 1928 and on completion of an internship at Letterman General Hospital, San Francisco, he received a regular commission as first lieutenant Aug.1, 1929. In 1942 he became staff surgeon for the eighth fighter command, which later moved to England. In 1944 he became staff surgeon for the second air division in England. In 1945 he became assistant surgeon for the Air Force training command at Fort Worth, Texas, and in 1948 was appointed surgeon for the air training command. In 1952 he became director of plans and hospitalization in the office of the surgeon general at Air Force headquarters, Washington, D. C. General McIlnay has been awarded the Legion of Merit, the Bronze Star medal, and Croix de Guerre with palm.

VETERANS ADMINISTRATION

Rehabilitation of Chronically Ill Veterans.—Chronically ill and aged veterans, hospitalized 10 to 20 years, are being rehabilitated and discharged from VA hospitals under an advanced concept of long-term patient care. Since the new program became operative about a year ago, 1,159 of the initial group of 4,263 long-term hospital patients have been discharged. Dr. I. J. Cohen, hospitals and clinics director, Veterans Administration, Washington, D. C., said, "A concerted effort is made to rehabilitate these chronically ill veterans sufficiently for them to be returned to their homes, to a foster home, or to other appropriate community facilities. Those for whom this is not possible continue to receive the care and treatment needed in as nearly a home-like atmosphere as it is possible to have in a hospital. The VA program," he added, "is an all-out effort by every branch of the hospital staff to rehabilitate long-term patients so they may achieve the best possible physical condition and maximum self-help, and to provide them with recreational, spiritual, and social activities so as to prevent mental regression and social isolation."

By grouping long-term patients on wards or sections, the hospitals are able to relax the rigid routine necessary on wards for acutely ill patients and to provide personnel especially trained in caring for the chronically ill. All VA general medical and surgical hospitals and some VA tuberculosis hospitals are caring for patients of this type, but 49 hospitals have special wards or sections for long-term patients.

FOOD AND DRUG ADMINISTRATION

Statement on Hoxsey Cancer Treatment.—The following statement was released Nov. 16 by G. P. Larrick, U. S. Commissioner of Food and Drugs.

"For the second time, a Federal court has determined that the Hoxsey medicines for internal cancer are worthless. Yesterday, after a six-week trial in the Federal court at Pittsburgh, the jury returned a verdict that these medicines, in pill form, were illegally offered as an effective treatment for cancer.

"The public should know, however, that this action does not end the menace of this fake treatment. It merely means that half a million of the Hoxsey pills, which were seized shortly after the opening of a second Hoxsey Clinic at Portage, Pa., will now be destroyed. An injunction is being sought to stop further interstate shipment of the pills. We intend to use every legal means within our power to protect consumers from being victimized by this worthless treatment.

"In the meantime it is of the utmost importance that cancer patients and their families, who may be planning to try the Hoxsey treatment either at Dallas, Texas, or Portage, Pa., should acquaint themselves with the facts about it. All such persons are advised to secure a copy of the Public Warning which was issued by the Food and Drug Administration last April [J. A. M. A. **160**: 1423 (April 21) 1956]. They may do this by writing to the Food and Drug Administration, Washington 25, D. C.

"Harry M. Hoxsey has continued to promote his worthless cure for more than 30 years, notwithstanding numerous local and state court actions. Proceedings under the Federal Food, Drug, and Cosmetic Act did not appear possible until a 1948 decision of the Supreme Court interpreting the word "accompanying" in the definition of labeling under the Act. An injunction suit was filed in 1950 and a decree finally issued by the Federal court at Dallas in 1953.

"Over the years thousands of persons have been deceived by the false claims for the Hoxsey liquid medicines and pills. At the Pittsburgh trial there was testimony concerning persons who may have died of cancer as a result of reliance on the Hoxsey treatment instead of seeking competent medical treatment in the early stages of their condition. The Government's evidence showed that alleged 'cured cases' presented by defense attorneys were people who did not have cancer, or who were adequately treated before they went to the Portage clinic, or died of cancer after they had been treated there."

Munford, Samuel Archer, Clifton Springs, N. Y.; born in Princeton, Ind., Dec. 14, 1876; Jefferson Medical College of Philadelphia, 1905; an associate member of the American Medical Association; past-president of the Seventh District of the Medical Society of the State of New York; medical advisor at Cornell University in Ithaca from 1910 to 1917; veteran of World War I; fellow of the American College of Physicians; chief of internal medicine at the Clifton Springs Sanitarium and Clinic from 1919 to 1948, when he became superintendent, serving until 1950; died Oct. 29, aged 79, of hypertensive cardiovascular disease.

Nadel, Samuel, Boston; Tufts College Medical School, Boston, 1920; member of the Massachusetts Medical Society; veteran of World War I; deputy commissioner of health for the city of Boston; for many years school physician; on the staffs of the Allerton Hospital in Brookline and the Harley Private, Boston City, St. Elizabeth's, Carney, and St. Margaret's hospitals; died in the Harley Private Hospital Sept. 10, and 59, of carcinoma of the pancreas.

Naegeli, Frank ⊕ Fergus Falls, Minn.; Northwestern University Medical School, Chicago, 1910; on the staff of the Lake Region Hospital, where he died Oct. 22, aged 82, of myocardial infarction.

Nelson, Frank Arleigh ⊕ Ajo, Ariz.; University of Nebraska College of Medicine, Omaha, 1923; medical superintendent and chief surgeon at the Phelps-Dodge Hospital; died Oct. 28, aged 58, of a heart attack.

Newton, Harlan Fay ⊕ Boston; born in Winchester, Mass., Feb. 8, 1895; Harvard Medical School, Boston, 1920; served on the faculty of his alma mater; member of the founders' group of the Board of Thoracic Surgery and the American Board of Surgery; member of the American Association for Thoracic Surgery; fellow of the American College of Surgeons; at various times on the staffs of the Middlesex County Sanatorium in Waltham, the Burbank Hospital in Fitchburg, and the Peter Bent Brigham Hospital, where he died Oct. 23, aged 61, of acute myocardial infarction.

Notbohm, William R. ⊕ Dousman, Wis.; Milwaukee Medical College, Milwaukee, 1898; for many years president of the Dousman State Bank; died Oct. 23, aged 90, of heart disease.

O'Connor, James Joseph ⊕ Alhambra, Calif.; Loyola University School of Medicine, Chicago, 1931; member of the Indiana State Medical Association; specialist certified by the American Board of Pediatrics; served on the staff of St. Catherine's Hospital in East Chicago, Ind.; died July 2, aged 54, probably of carcinoma of the pancreas and diabetes mellitus.

Rastatter, Paul F., Jackson, Miss.; Baltimore University School of Medicine, Baltimore, 1902; past-president of the Crawford County (Pa.) Medical Society; at one time medical director of Crawford County, Pennsylvania; served on the staffs of the Spencer Hospital in Meadville, Pa.; and St. Vincent's Hospital in Erie, Pa.; died Oct. 12, aged 80, of heart disease.

Ritchey, Billy Fay, Yonkers, N. Y.; State University of Iowa College of Medicine, Iowa City, 1921; served on the staff of the Yonkers General Hospital; formerly medical examiner in the Yonkers public schools; died in the Montefiore Hospital, New York City, Sept. 24, aged 60, of cerebral thrombosis.

Robinson, Edward Percy, Seaside Park, N. J.; Bellevue Hospital Medical College, New York City, 1897; also a pharmacist; died Oct. 13, aged 85, of chronic myocarditis.

Robinson, William Ashby, Old Fort, N. C.; University College of Medicine, Richmond, Va., 1900; served on the staff of the Marion (N. C.) General Hospital; died Aug. 24, aged 78, of heart disease.

Russell, John Colvin ⊕ Detroit; Detroit Homeopathic College, Detroit, 1906; on the staffs of the Grace and North Detroit General hospitals; died in the Mount Carmel Mercy Hospital Sept. 20, aged 77, of carcinomatosis.

Russell, Rosannah, Fort Shaw, Mont.; Northwestern University Woman's Medical School, Chicago, 1900; an associate member of the American Medical Association; died in Great Falls Sept. 27, aged 88.

Schreier, Alexander Rainold, Gillett, Texas; Creighton University School of Medicine, Omaha, 1911; died in the Kenedy Clinic and Hospital in Kenedy Aug. 16, aged 70, of virus pneumonia.

Shepherd, Robert Herbert, Jasper, Ala.; Birmingham Medical College, Birmingham, Ala., 1910; member of the Medical Association of the State of Alabama; died in the Walker County Hospital Sept. 9, aged 70.

Shepherd, Samuel Tinson, Birmingham, Ala.; Atlanta College of Physicians and Surgeons, Atlanta, Ga., 1902; died Sept. 15, aged 80, of carcinoma of the lip with metastasis.

Shultz, Cameron, Danville, Pa.; Jefferson Medical College of Philadelphia, 1892; an associate member of the American Medical Association; served as secretary of the Montour County Medical Society and Danville Board of Health; during World War I medical examiner for the draft board and a member of the Medical Corps of the National Guard; died in the George F. Geisinger Memorial Hospital and Foss Clinic Sept. 19, aged 85, of acute myocardial infarction.

Smith, J. Lewis, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1905; for many years surgeon for the Southern Railway; died in the South Carolina Baptist Hospital Sept. 12, aged 74.

Steele, Guy, Cambridge, Md.; University of Maryland School of Medicine, Baltimore, 1897; past-president of the Medical and Chirurgical Faculty of Maryland; served as county health officer, and was associated with the U. S. Public Health Service, for many years on the staff of the Cambridge-Maryland Hospital, where he died Oct. 12, aged 95, of complications following fracture of the hip.

Stieglitz, Leopold, New York City; Universitat Heidelberg Mediziniche Fakultät, Baden, Germany, 1891; an associate member of the American Medical Association; holder of the first medical license issued by New York State; the Leopold Stieglitz visiting professorship was established at the New York University College of Medicine in 1947 by his friends and patients and provides funds for an annual visiting professor to the school, died Oct. 7, aged 89.

Swift, Charles Frederick, Jordan, N. Y.; University of Michigan Homeopathic Medical School, Ann Arbor, 1904; served as coroner and health officer in Broome County; died Sept. 22, aged 74, of cerebral hemorrhage and arteriosclerosis.

Turrell, Guy Hanford, Smithtown, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1896, an associate member of the American Medical Association; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; president of the Smithtown Library; on the staffs of the Southside Hospital in Bay Shore and the Central Islip (N. Y.) State Hospital; died in the Ross Sanitarium, Brentwood, Oct. 7, aged 84, of cerebral hemorrhage.

Uphouse, Albert Milton, Stoystown, Pa.; Eclectic Medical Institute, Cincinnati, 1909; formerly county commissioner and coroner; for many years a member and president of the school board, on the staff of the Somerset (Pa.) Community Hospital, died in the Windber (Pa.) Hospital Sept. 20, aged 79, of cardiac decompensation.

Wells, Charles Obed ⊕ Hillsboro, Ore.; University of Oregon Medical School, Portland, 1943; died near Joseph Oct. 6, aged 54, of coronary occlusion.

Wilcox, John Constantine, Mulvane, Kan.; University of Louisville Medical Department, Louisville, Ky., 1907; died Sept. 25, aged 76.

Young, James Watson ⊕ Beverly Hills, Calif.; State University of Iowa College of Medicine, Iowa City, 1926; member of the American Academy of General Practice; served on the staff of the California Hospital in Los Angeles, where he died Oct. 15, aged 55, of rheumatic heart disease-with mitral stenosis.

Zimmering, Paul, New York City; University of Bristol Faculty of Medicine, Bristol, England, 1937; member of the American Psychiatric Association and the Medical Society of the State of New York; specialist certified by the American Board of Psychiatry and Neurology; veteran of World War II; senior psychiatrist of the male adolescent ward of Bellevue Hospital; died in the Mount Sinai Hospital Oct. 16, aged 47.

FOREIGN LETTERS

AUSTRIA

Treatment of Thrombosis.—At the meeting of the Vienna Society of Physicians on Oct. 19, Gottlob and Zinner stated that large doses of streptokinase given in the attempt to dissolve a thrombus may cause toxic reactions. Doses about 1/100 the size of those usually given are sufficient, if the enzyme is applied as a continuous infusion topically into veins peripheral to the thrombosed area. Symmetrical thromboses in the femoral veins were produced in cats. One side was infused with streptokinase and the other with Ringer's solution. The thrombus was dissolved only on that side where an infusion of 80 units of the enzyme per kilogram of body weight per hour was given. The thrombosis recurred after the treatment was discontinued or after the sides receiving the infusions were reversed. The speakers concluded that thrombolysis is limited to the veins of the treated side and that further therapy with anticoagulants is necessary after the infusions are discontinued. Excellent results were obtained in nine patients with superficial or deep thrombosis with a dosage of 1.5 to 15 units per kilogram of body weight per hour. Improvement was observed within six hours after treatment was started. Mild pyrogenic reactions were observed and were attributed to the toxic effects of the streptokinase-streptodornase infusion rather than to the fibrinolysis.

BRAZIL

Stenosis of the Stomach.—Dr. Mario Fanganiello and co-workers in *Revista paulista de medicina* (49:93, 1956) reported a series of 24 patients with stenosis of the stomach caused by the swallowing of caustic substances. In 20 patients the swallowed substance was caustic soda used for house cleaning purposes; in 2, hydrochloric acid; and in 2, more complex caustic compounds. Of the 20 lesions caused by caustic soda, the stenosis was in the pylorus in 6; in the antrum in 6; in both pylorus and antrum in 2; in the gastric fundus in 2; in the pylorus, antrum, and gastric fundus in 3; and in the antrum and gastric fundus in one. In all of these there was also stenosis of the esophagus. In the 11 patients with pyloric stenosis the lesion was manifest after a minimal lapse of 19 days and a maximal lapse of 31 months. The pyloric stenosis caused a rapid and marked dehydration and electrolytic imbalance necessitating a prompt correction. Its diagnosis is not difficult, except when the symptoms are masked by those of a stenosis of the esophagus. The diagnosis was confirmed by x-ray. The roentgenogram may show the stomach greatly diminished in volume or, when there is a prolonged stasis, somewhat enlarged, the first manifestation being the commoner. Peristalsis was always diminished. The mucosal pattern was greatly altered; in certain areas no rugae could be seen, and in others there was a thickening and edema of the mucosal folds, with a variable degree of infiltration-causing strictures. Some areas that were not destroyed showed proliferations accompanying the reparative process that appeared as small polyps carpeting the antral mucosa. Gastric neoplasms had to be ruled out. In patients in whom the pyloric obstruction appears a few years after swallowing the caustic substance, the patient may not relate his symptoms to the injury and may even forget to speak of it. Treatment consists of segmental or partial resection of the stomach.

Endoscopy in Cancer of the Esophagus.—Dr. J. A. Botelho of São Paulo at a meeting of the Associação Paulista de Medicina reported a series of 192 patients with tumors of the esophagus found in 7,100 admissions to the surgical service of the São Paulo State University Hospital. Of these tumors, 19 were in the upper third of the esophagus, 48 in the middle third, and 90 in the lower third; in 35 patients the location was not recorded. The diagnosis was made by esophagoscopy and biopsy. The speaker agreed with Vinson's statement that any firm obstacle at the level of the cardia should be considered as cancer. Dr. Botelho's experience shows that the tumors of the cardia are sometimes undiscovered even after several x-ray examinations. Esophagoscopy may not visualize the tumor, but a permanent obstacle at the level of the cardia should cause the endoscopist to suspect cancer. A possible accident in performing a biopsy of the esophagus is perforation. Anatomic peculiarities make perforation more likely in the first and last portion of the esophagus than in the middle section. In 192 biopsies performed by the author perforation occurred only once. No more tissue than is strictly necessary should be taken. The speaker never tries to go beyond the tumor with the esophagoscope or with catheters to estimate the extent of the growth, since the x-ray examination gives better information in this respect. If perforation of the esophagus is suspected, the ambulatory patient is advised to come back to the clinic without delay if there is fever or persistent pain. With the use of antibiotics the prognosis in such patients is greatly improved.

Tropical Eosinophilia.—The relationship between climate and asthma has long been recognized. Climatic factors influence asthmatic patients by different mechanisms and to a varying degree. Its importance in the determination or the aggravation of some cases is so great that such cases are commonly designated as climatic asthma. The term "tropical eosinophilia" was first used by Weingarten, in 1943, when he reported 81 cases occurring in India. For several years cases have been reported in the northeastern tropical section of Brazil. Dr. A. Coutinho in *O Hospital* (50:575, 1956) reports a series of 80 patients in Recife with this condition. Of these patients, 11 were children varying in age from infants to 9 years, 9 were 10 to 19 years of age, 12 were 20 to 29, 19 were 30 to 39, 16 were 40 to 49, 10 were 50 to 59, 2 were 60 to 69, and one was between 70 and 79. In 8 patients the duration of the symptoms was less than one month; in 45, 1 to 12 months; in 23, 1 to 5 years; and in 4, more than 5 years. Dr. Coutinho did not find evidence of any allergic cause. He describes tropical eosinophilia as a chronic benign process with cyclic nocturnal paroxysms of nonproductive persistent coughing with variable amounts of wheezing and expiratory dyspnea, sometimes preceded or accompanied by loss of weight, fatigue, fever, anorexia, thoracic pains, and upper respiratory symptoms. A diffuse mottling or an accentuation of bronchovascular striations and a hilar enlargement were the usual roentgenographic manifestations. The essential feature of the disease was an intense eosinophilic leukocytosis. Other common features were eosinophilic hyperplasia of bone marrow, an increased sedimentation rate, and negative tests for syphilis or any parasitic disease. In Recife the mean maximum temperature is 83.5 F, the mean minimum temperature is 73.9 F, and the total annual rainfall is 60.5 in.

FRANCE

Novobiocin.—R. Martin and co-workers (*Presse méd.* 64:1597, 1956) say that novobiocin, a new antibiotic, possesses an outstanding antimicrococcic action. The micrococci easily acquire, both in vitro and in vivo, resistance to the drug, but this resistance does not induce any cross resistance to other antibiotics. The bacteriostatic activity of novobiocin is impeded by alkalinity or by the presence of serum. The antibiotic becomes reversibly attached to the albumin fraction of the serum, but the bactericidal potency of the free portion remains intact. Novobiocin showed a bactericidal potency intermediate between that of penicillin and that of erythromycin in vitro against strains of micrococci. This potency was compared in vivo, by means of a quantitative test, with that of penicillin, erythromycin, and chloramphenicol and gave results similar to those obtained with penicillin. There was a bactericidal synergy between novobiocin and penicillin and between novobiocin and streptomycin, but when the new drug was given with antibiotics of the erythro-

The items in these letters are contributed by regular correspondents in the various foreign countries.

mycin group, it provided only an additive and bacteriostatic effect. The authors reported a patient with severe micrococcic endocarditis in whom the use of a combination of penicillin and novobiocin was much more effective than had been the previous use of penicillin alone.

Icterus Caused by Inhibition of the Biliary Secretion.—I. Pavel (*Presse méd.* 64:1600, 1956) states that some cases of icterus considered to originate from hepatitis are due to functional inhibition of the biliary secretion. Of the patients he personally observed, he cites the condition of one as particularly illustrative. The icterus was shown to be prolonged, with no tendency toward remission, and accompanied by intractable pruritus in a 25-year-old man. On operation, no biliary obstruction was found and the biliary ducts were not dilated. When cholecystostomy was performed, the dark bile started flowing as early as the first hours after the operation, the pruritus disappeared, and the feces resumed their normal color. Such an icterus could not have been caused by hepatitis, because the bile flow reappeared in much less time than would be necessary for the healing of an anatomic lesion. Nor is it possible to attribute the icterus to an intrahepatic obstruction (biliary thrombus, external pressure on the canals of Hering, or increased permeability to the pigments in the latter) in view of the prompt return of the biliary secretion. The only explanation is functional inhibition of the biliary secretion.

Frenquel in Psychiatric Therapy.—H. Collomb and co-workers (*Presse méd.* 64:1602, 1956) treated 30 patients with Frenquel. They made the following conclusions: 1. To the first indications for its use (delirious and hallucinatory states) one should add the depressive state. 2. Its action proves spectacular in only a few patients, and it is difficult to predict which patients will benefit. 3. It is nontoxic, and further observation is necessary for defining more accurately its indications for use and its value as an adjuvant to other treatments.

Combined Anti-Inflammatory and Antituberculous Chemotherapy.—Pestel and Ravina (*Presse méd.* 64:1615, 1956) recommend combined therapy with phenylbutazone and isoniazid for all forms of tuberculosis where the inflammatory character of the lesions seems to predominate. They call attention to the fact that this mode of treatment not only is of value in such cases but also has proved effective in patients with pulmonary infiltrates, tuberculomas, progressive exacerbations, ulcerocavitary tuberculosis resistant to the usual therapeutics, and osseous or articular localizations of the disease. In the authors' series of 32 patients the results proved as good as those with the hormonal therapy, without any of the untoward side-effects imputed to the latter, such as dissemination or lighting up of old foci of infection. The combination therapy was well tolerated, and the treatment shortened the febrile course of the disease.

Chemotherapy of Psychoses.—Puech and Robin (*Semaine hôp. Paris* 32:3252, 1956) studied the results obtained with the use of chlorpromazine therapy and with "sleep cure" in a series of 80 women with various psychoses. Chlorpromazine was given intramuscularly for 10 days in doses of 75 to 125 mg. daily, then by mouth in slowly decreasing doses of 200 to 100 mg. daily. Sleep was not sought in those treated with this drug. The sleep cure was conducted in quiet, darkened rooms. Sleep was maintained by the administration of narcoleptic drugs and barbiturates. The daily duration of the sleep was 14 to 15 hours. The effects were studied according to the nature of the syndrome, the duration of the disease, the age of the patient, and the causative factors. Both therapy with chlorpromazine and the sleep cure proved effective in the course of polymorphic delirious exacerbations and acute delirious states. Chlorpromazine should be reserved for the forms of psychosis accompanied by agitation. In depressed states, therapy with chlorpromazine and the sleep cure were almost equally effective. Untoward effects were rare.

Vital Statistics.—In 1955 there were 313,000 marriages, 802,000 births, and 523,000 deaths, compared with 314,000 marriages, 807,000 births, and 515,000 deaths in 1954. In 1955 the death rate for infants under 1 year of age was 34.2 per thousand births compared with 36.6 in 1954.

Premature Cesarean Section.—In the March issue of *Gynécologie et obstétrique* A. Rossier and co-workers reported a series of 123 cesarean sections performed before term because of eclampsia or placenta previa. The infant mortality was 28%. In 53% of the series, the infants had to be resuscitated. The mortality rate was 66% for those premature infants whose birth weight was under 2 lb. (1,000 gm.). Close collaboration between obstetrician and pediatrician improves the infant's chances of survival.

Life of Erythrocytes in Hereditary Spherocytosis.—In the *Revue d'hématologie* (no. 2, 1956) A. Strumpf reports on the transfusion of spherocytes (1) to normal subjects whose spleen has been removed, (2) to subjects suffering from hereditary spherocytosis whose spleen has not been removed, and (3) to subjects suffering from spherocytosis whose spleen has been removed. In normal subjects whose spleen has not been removed, the life of the erythrocytes is 10 to 15 days; it reaches 100 days in normal subjects and those suffering from spherocytosis after splenectomy, but in patients with spherocytosis whose spleen has not been removed, erythrocytes survive only about 3 days. The author concludes that hereditary spherocytosis is caused by an abnormality of erythrocytes. Splenectomy relieves all the symptoms of the disease except spherocytosis.

Treatment of Tuberculosis with Nylon Nets.—In *Lyon chirurgical* for January, 1956, D. Juzbasic reports a series of 18 patients in whom the pulmonary lobe affected with tuberculosis is enveloped in a nylon net. The operation is simple. After the lobe is freed from any adhesions, it is wrapped in a net tightened around the hilus with a string. The wrapping is thus hermetic. Experiments on animals showed that the lobe is thus made void of air and collapses. After the operation, tubercle bacilli in the sputum disappear, the patients' health improves, and, four months after the operation, they may resume their occupations No complications were observed in these patients.

The Menopausal Syndrome.—In *La semaine des hôpitaux de Paris* for Aug. 26 (page 2777) Mrs. L. W. Halle, who noted that there has been an increase in the intensity and duration of menopausal disorders in recent years, presents the results of a survey of 2,000 native African women. In general, no subjective menopausal disorders were observed in women who had had no contact with Europeans, and an increase in the incidence of these disorders proportionate to the extent of the contact was seen in those who had had such contact. The author concludes that psychic as well as hormonal factors play an important role in causing menopausal disorders.

Endocarditis due to Vibrio Fetus.—Human infection with Vibrio fetus is relatively rare. L. Auquier and co-workers have reported a case in a 44-year-old man who complained of a severe headache and showed signs of septicemia. The organisms were identified with difficulty in a blood culture. The bacillus is gram-negative, thin, and actively motile. On the 10th day of the patient's hospitalization, a holosystolic souffle was noted. The authors believed the infection was caused by eating contaminated horse meat.

INDIA

Combined Primaquine Treatment of Malaria.—R. N. Chaudhari and co-workers (*Bulletin Calcutta School of Tropical Medicine*, July, 1956) report a series of 48 patients showing a fair number of asexual parasites in the blood. Five patients were given primaquine phosphate combined with chloroquine phosphate; 18 were given primaquine and amodiaquine hydrochloride; and 25 were given primaquine and quinine sulfate, all in single doses for three days. Included in the series were 14 patients with falciparum malaria, 32 with vivax malaria, one with a mixed infection, and one with malariae malaria. In the 18 patients treated with primaquine and amodiaquine, the fever subsided, with disappearance of asexual parasites, in 16 of them within two days and in 2 of them within three days Sexual parasites disappeared in 12 patients within two days and in 4 others within three to five days. The other two patients had no gametocytes in their blood. In the five patients treated with chloroquine and primaquine, the fever subsided, with disappearance of asexual parasites, within two days, and the sexual parasites disappeared in four of them within two days and in the other one within three days. In the group receiving quinine and primaquine the fever subsided, with disappearance of asexual parasites, in 21 in two days and in the other 4 in three days. Of the 20 patients who had gametocytes in their blood, these forms disappeared from 15 in 2 days, from 4 in 3 to 5 days, and from the other one in 10 days after completion of the treatment. No toxic reactions were observed.

Rhabdomyosarcoma of Spermatic Cord.—Rhabdomyosarcomas arising from the spermatic cord are very rare. D. B. Reddy and co-workers (*Journal of the Indian Medical Profession*, Oct., 1956) observed such a tumor in a 30-year-old man, who, when first seen, complained of a swelling of the right side of the scrotum of 12 years' duration and pain and a tumor in the abdomen of about three months' duration. The right testis could be felt separate from the scrotal tumor. A right orchiectomy was performed. The nodular tumor was 4 in. in diameter and large vessels were seen on its surface. Cut section showed it to be orange in color, to be soft in consistency, and to have areas of necrosis and hemorrhage. It was well circumscribed. The testes and epididymis could be identified, the tumor having its origin in extratesticular tissue. Microscopic examination revealed polymorphic areas consisting of cells of various shapes and sizes. Some were round with a central nucleus; others were ribbon-shaped showing cross striations. This established the diagnosis of rhabdomyosarcoma of the spermatic cord.

Malignant Melanoma in Indians.—M. V. Sirsat (*Indian J. M. Sc.* 10:629, 1956) reported a series of 60 cases of malignant melanoma. In every case the diagnosis was established by histological examination. Forty-five patients were in the age group 31 to 60; only one was prepuberal. In the series, 42 were male and 18 female. The tumor had arisen from the skin in 31, the commonest site being the sole of the foot. Cutaneous carcinomas other than melanomas are rarely found on the plantar aspect of the foot. A history of preexisting nevi was present in 36 to 80% of the patients. In 24, the tumor arose primarily in the mucosa of the mouth, nose, esophagus, anorectal region, or vagina. In two patients the primary site was unknown, and in one of these a metastatic tumor was found in the breast.

Carcinoma of the Breast.—Reddy and Reddy (*Indian J. M. Sc.* 10:642, 1956) state that one explanation for metastasis in malignant growths is that a diminished content of calcium in the malignant cells lowers their adhesiveness. The authors estimated the calcium content of malignant cells in primary carcinomas of the breast, their metastases, and normal breast tissue and found the calcium content of the cells in the primary and secondary tumors definitely lower than that of normal tissue. This was especially true of the metastases. Changes in the stroma may also be responsible for the dissemination of malignant growth. These changes were also studied in the same specimens by staining with toluidine blue and aminosalicylic acid. In nearly 40% of the cases studied, for example, as in the case of benign breast tumors, there was metachromasia that could not be removed by digestion with hyaluronidase. This could be due to some change in the ground substance allowing the malignant cells to infiltrate through.

Treatment of Gonorrhea with Chloramphenicol.—S. N. Ranade and co-workers (*J. Indian M. A.* 27:242, 1956) gave intramuscular injections of chloramphenicol to 22 patients with chronic gonococcic urethritis in whom other antibiotics had failed to effect a cure. Thirteen patients were given a total dosage of 3 gm. and nine a total dosage of 1 gm. in three divided doses on alternate days. The results were evaluated on the basis of urethral smears, culture of urethral discharges, smear examinations after prostatic massage, culture of prostatic discharges, and urine examination. Criteria for cure were symptomatic improvement, cessation of urethral discharge, absence of gonococci in the smear and culture of the urethral and prostatic discharges, presence of less than three pus cells in prostatic smears, and normal urine sediments. With the 1-gm. dosage schedule, the failure rate was nearly 3.5 times as great as that with the 3-gm. dosage schedule. The apparent cure rate on the 3-gm. dosage schedule was 85%.

Cytology of the Oral Cavity.—Peters and Rijsinghani (*J. Indian M. A.* 27:231, 1956) report the results of smears from the oral cavity of 595 patients with different diseases of the mouth. Smears taken from an area that harbors a cancer are usually rich in cells. In this group, 194 patients had oral carcinoma. The diagnosis was verified histologically unless it was far advanced. Biopsy specimens were obtained from 185 patients of whom 162 showed cancer on histological examination. Smears were taken from all patients. One hundred fifty-four showed malignant cells; 8 failed to show malignant cells, although a carcinoma was present; and 32 showed cells probably but not positively identified as carcinomatous. Of those patients with diseases other than carcinoma, 15 had leukoplakia, 19 had submucous fibrosis, 2 had rhinoscleroma, and the rest had such disorders as infections, ulcers, and vitamin deficiencies. In two patients, cancer was first discovered by smear, the lesions having been considered ulcerative stomatitis and hypertrophy of the tonsil respectively. A biopsy specimen in these cases revealed carcinoma. Cells desquamated by oral cancer are sufficiently characteristic to be recognized in the smear.

Employees State Insurance Plan.—The government has decided to extend the medical care under the Employees State Insurance Scheme to families of insured persons. The cooperation of the state governments is being sought to carry out the decision as early as possible. Another 3 million persons are likely to benefit when the medical care is extended to the family. The plan now covers more than 1 million employees. It will ultimately cover more than 9 million persons, including families, when extended to all of India. Under the act, insured persons are already paying the full contribution of about 2.5% of their wages, while employers are paying less. Though under the act the employers' contribution up to 5% of the total payroll can be exacted, employers have been required to pay only 1.75%. With the proposed extension of the medical care to the families of the insured employees, the rates of contribution from employers will be increased to 2.5%.

Less Familiar Forms of Leprosy.—H. W. Wade in the April issue of *Leprosy in India* states that the clinical findings in leprosy may vary in different countries or under different circumstances in the same country. Classification has become complex and is becoming more so as new forms are identified. The primary basis of classification should be clinical. The "intermediate" form is characterized by simple flat macular lesions that are early as regards development and uncertain as regards future evolution. Some will become tuberculoid, some lepromatous, and some will persist as simple macular lesions. The minor and major varieties of the tuberculoid type are relatively quiescent. Two kinds of reactions in this form are distinguished: (1) tuberculoid reactivation, which is primarily an acute activation of preexisting tuberculoid lesions, and (2) reactional tuberculoid leprosy, an abruptly developing condition. The recently recognized borderline form develops in patients with the tuberculoid form as a result of repeated or severe reactions that overcome the patient's resistance. It is often diagnosed as lepromatous because of its bacteriological positivity and lepromin negativity, but it has certain distinctive features. The condition of many patients is difficult to classify because it shows intermediate characteristics. The principal difficulty is the distinction between borderline and lepromatous cases.

Serum Iron in Visceral Leishmaniasis.—C. R. Das Gupta and co-workers (*Bulletin Calcutta School of Tropical Medicine*, July, 1956) state that anemia of a varying degree is seen in visceral leishmaniasis. The use of hematinics alone, without specific treatment, rarely, if ever, improves the blood picture. Other factors in the causation of this anemia are hypersplenism, hemolysis, and associated nutritional deficiencies of iron or antimegaloblastic factors. Other authors have shown that the serum iron and iron binding capacity of the serum are low in chronic infections. The present study was undertaken to see whether the anemia of leishmaniasis conforms to the pattern seen in chronic infection. Studies of the serum iron, iron binding capacity, and iron absorption of 29 patients with this disease were made before and after the specific treatment was started. In untreated patients these values were low as compared with those in patients with other chronic infections. There was, however, no significant correlation between the degree of anemia and the degree of depression in the values. After specific treatment, the iron binding capacity and absorption values improved, but in many the serum iron remained low. These findings indicate that, in addition to hematological values, the serum iron level can serve as an additional index of improvement. The results show that chronic infection plays a significant part in the causation of anemia in leishmaniasis.

Cutaneous Nocardiasis.—Chakraborty and Banerjee (*Bulletin Calcutta School of Tropical Medicine*, July, 1956) observed six patients with cutaneous actinomycosis in four of whom the organism was isolated and identified as belonging to the genus Nocardia. Two patients treated with sulfonamides, various antibiotics, potassium iodide, and x-ray did not respond and died of the disease. The third showed 25% improvement when put on therapy with isoniazid and aminosalicylic acid. The fourth, who had had a swelling of the left ankle with multiple sinuses for about six years, appeared to have improved clinically after five and a half months of the same treatment, but he still complained of occasional pain in the leg and restriction of movement of the involved ankle.

Synthetic Drugs for Cholera.—Lahiri and Guha (*J. Indian M. A.* 27:161, 1956) reported that earlier investigation with a crude extract named thiodiamine, obtained from the decomposition products of the barks of Crataeva roxburghii, showed good antibacterial action against Vibrio comma. Elucidation of its structural formula prompted the investigation of some related compounds, generally of phenyl and diphenyl linkages, for antibacterial properties. Four of them (orthothiocarbamidophenol, 4'-4'-dihydroxythiocarbamidophenol, ortho-aminophenol, and para-aminophenol) were found to have marked antibacterial effects against V. comma in vitro. They also showed, in varying degrees, antibacterial actions against Streptococcus hemolyticus, Micrococcus pyogenes var. aureus, Shigella shigae, and Salmonella typhosa. They had no action against Escherichia coli. They were also found to have very low toxic effects when orally administered to rabbits for a short time. On clinical trial in the treatment of cholera, their effects on death rates were inconclusive. In severe infection the antibacterial effect of para-aminophenol on stool cultures taken every four hours was found to be practically equal to that of sulfaguanidine or oxytetracycline. The effect of ortho-aminophenol appeared to be a little less. These compounds, especially the aminophenols, were not recommended for wider use without further trial.

Treatment of Malaria.—M. N. Jinda (*J. Indian M. A.* 22:204, 1956) states that an earlier experimental study on the toxicity of quinine-calcium glucono-galacto-gluconate (QCGGG) on the cardiovascular system of dogs had shown that this drug is much safer when administered parenterally as compared with quinine. He has now given a 10% solution of QCGGG intravenously to 40 patients with proved malaria. The dosage was calculated according to the age of the patient. Blood smears were checked on the fourth day and subsequently every week for four weeks. Clinical cure was obtained in 30 of these patients. The drug was found effective against Plasmodium vivax and Plasmodium falciparum but was ineffective against their gametocytes. It is not recommended for the routine treatment of malaria.

Hyperplastic Intestinal Tuberculosis.—K. L. Wig and co-workers (*Indian Journal of Tuberculosis*, September, 1956) state that an earlier investigation revealed many of the chronic granulomatous lesions of the ileocecal region to be tuberculous in origin. Although these lesions may not show the typical histopathological appearance of tuberculosis and no organisms could be isolated, the findings may change, with or without specific antituberculosis treatment, in favorable cases with progress of the disease. The authors, therefore, obtained, in a series of 42 patients, roentgenograms of the chest and gastrointestinal tract, cultures of sputum and gastric washings for acid-fast bacilli, and bacteriological and histopathological examination of the mesenteric nodes and resected loops of the small and large intestine. Clinically, most of the patients complained of a dull abdominal aching pain with acute exacerbations. Symptoms, signs, and radiologic examination pointed to a diagnosis of chronic intestinal obstruction. In group 1, consisting of 14 patients, the diagnosis was established by the isolation of Mycobacterium tuberculosis and by histopathological examination. In group 2 (14 patients) typical histopathological findings were observed but no organisms were isolated. In group 3 (14 patients) neither the bacteriological nor the histopathological findings were diagnostic, but, taken in conjunction with the clinical features and the presence of small caseous areas in some patients, these lesions were considered tuberculous in origin. Typical histopathology is not always seen, and nonspecific round cells and plasma cells may be the only evidence of tuberculous inflammation, particularly of mucous membranes. Most of the patients had had prolonged antituberculosis treatment, and healing had already started in many of them.

Paper Electrophoresis.—M. K. K. Menon and co-workers (*Journal of Obstetrics and Gynaecology of India*, June, 1956) state that serum protein values of normal nonpregnant women cannot be taken as normal standards for those who are pregnant. An investigation was therefore undertaken to obtain standard figures for the serum protein values at the full term of pregnancy and to compare those values with others obtained in women whose pregnancies were complicated. The study included 8 normal nonpregnant women of the same age group, 52 women with normal pregnancies at full term, 16 with anemia complicating pregnancy, and 13 with eclampsia complicating pregnancy. Serum protein fractions were estimated by paper electrophoresis In women with normal pregnancies at term there was a statistically significant drop in the total proteins, which was mainly due to the fall in the albumins. There was a slight rise in the serum alpha$_1$, alpha$_2$, and beta globulin values. There was no change in the serum gamma globulin value at full term. In eclampsia there was a further drop in the total proteins and albumins. The alpha$_1$, alpha$_2$, and beta globulin values showed no significant change. The lowest values of gamma globulin were obtained in eclampsia, and the fall was statistically significant. In pregnancies associated with anemia and hypoproteinemia there was a significant fall in all the fractions except alpha$_1$ and gamma globulins.

Late Abortions.—H. V. Tilak studied a series of 600 patients with abortion occurring after the fourth month of pregnancy (*Journal of Obstetrics and Gynaecology of India*, September, 1956). Of these patients, 311 were found to suffer from one or more conditions that usually cause abortion. The Rh factor played little or no part in isoimmunization of the mother to cause abortion. Nephritis was also a negligible factor. Seminal defects was a major cause if the finding of abnormal sperms in 44, or 46%, of 95 seminal specimens is applied to the series as a whole Excessive torsion or twisting of the umbilical cord was found in 12% of the cases in which the products of conception were available for inspection. Excessive twisting seems to be a cause and not a result of maceration of the fetus. The frequency and variety of pathological conditions in the placenta was an outstanding finding in this inquiry. It was found in 30% of the cases in which the products of conception could be studied. A combination of some unhealthy factors before and during pregnancy seems to increase the risk of abortion. Complete general and local examination and treatment before conception of married persons who complain of long sterility or repeated abortions, stillbirths, and premature deliveries is an important step in reducing the incidence of late abortions. The inquiry points to the importance of antenatal care and treatment of mothers from the time pregnancy is first suspected, with a view to remedying as many of the devitalizing factors as possible.

Adrenal Cortical Causes of Toxemia of Pregnancy.—R. K. K. Tampan and co-workers (*Journal of Obstetrics and Gynaecology of India*, September, 1956) investigated the activity of adrenal cortex in normal nonpregnant women, normal pregnant women, and women with toxemias of pregnancy. Significant increase in the corticosteroid excretion was noted in patients with toxemia of pregnancy. This excretion returns to normal in the postpartum period when the toxemia has subsided. A close inverse proportionate relationship between the sodium-potassium excretion ratio and the formaldehydogenic steroid similar to the relationship exhibited by aldosterone was demonstrated. Severe pyridoxine deficiency was shown to cause morphologic changes in the adrenal cortex, which returns to normal after injections of pyridoxine. Other factors of the vitamin B complex cause similar changes. A deficient niacin intake was found in patients with preeclampsia and eclampsia. This defect may be the initial stimulus resulting in enlargement of the zona fasciculata of the adrenal cortex, with increased production of corticosteroids. This, in turn, by inhibiting the production of progesterone, causes premature maturation of the placenta, producing an enzyme that ultimately acts adversely on the vascular and renal systems. Vitamins, to be effective in the prevention of toxemia, should be given in the first month of pregnancy, as such supplements may fail to reduce the incidence of preeclampsia and eclampsia once the placenta is formed.

NORWAY

Testing of New Drugs.—At an Inter-Scandinavian medical conference last summer a discussion centered about the merits and ethics of double-blind testing of new remedies. Prof. O. J. Broch of the University of Bergen stated his views on the subject in the daily newspaper, *Aftenposten*, for Oct. 5. He recalled that a few years ago the world at large was tricked into believing in fantastic claims on behalf of chlorophyll, which was not tested by this method. It is ethically indefensible to give inert tablets when the drug to be tested has self-evident merits and the disease in question is serious, but the situation is somewhat different when the merits of a certain remedy are in doubt and its prolonged use is costly. As a case in point, Professor Broch referred to the treatment of angina and other manifestations of heart disease with anticoagulants. Were this treatment to be applied wholesale to such patients, the cost to the community would be enormous and the patients would have to submit to tedious years of close medical supervision. Here, then, is a field in which the judicious treatment of alternate patients should help to clarify matters. Anticoagulants have proved useful in certain diseases, but we have yet to learn exactly which they are and under what special conditions. Professor Broch concludes that we are not justified in dispensing with this test for distinguishing between potent and impotent remedies.

The Choice of Site of BCG Vaccination.—The BCG laboratory in Bergen acts as a clearing house for information on BCG vaccine. Its latest advice is to shun the thigh as a site for vaccination because of the greater risk of severe local reactions and regional adenitis after an intracutaneous injection. The outer aspect of the upper part of the arm is to be preferred, and whoever insists on vaccination of the thigh should be warned of the risk.

Smallpox Vaccination.—The new smallpox vaccination law that came into force on July 1, 1955, was framed to encourage such vaccination early in life to reduce the risk of postvaccinal encephalitis to the minimum. According to this law vaccination should be carried out before the end of the calendar year following that in which a child is born. The sponsors of this law also emphasized the importance of educational propaganda addressed to the educated as well as to other elements of the community. An investigation undertaken by Dr. K. H. Torp (The Journal, Dec. 24, 1955, page 1675) showed that the medical profession does not set as good an example in this respect as it should, but early vaccination has of late been more popular than it was, to judge by a study of the subject published in *Tidsskrift for den norske lægeforening* for Oct. 1 by Dr. T. Bjerkedal, who has scrutinized the vaccination records of school children in Oslo. Four schools, representing different social strata, were studied, and the parents were graded in four different groups according to their social standing. The lowest social group had the lowest vaccination rate, and 62% of the total of 4,608 children had already been vaccinated. About 53% of the vaccinated children had been under the age of 2 years when vaccinated. What was encouraging and indicative of the value of popular health propaganda in recent years was the rise in the relative number of early vaccinations. Thus only 33.5% of the children born in 1941 had been vaccinated under the age of 2, as compared with 63.9% of those born in 1947.

Fibrositis of the Breasts.—Dr. H. Schartum-Hansen has found that the pain and tenderness associated with chronic fibrositis of the breasts tend to disappear after only a few days' treatment with corticotropin (*Nordisk medicin*, Oct. 25). The four patients in his series ranged from 20 to 36 years of age, and the total dosage of the drug, given for five to nine days, ranged from 0.6 to 1.0 gm, the initial dose being from 100 to 200 mg. The disappearance of pain and tenderness coincided in some patients with diminution or disappearance of palpable swellings.

UNITED KINGDOM

Smoking and Cancer of the Lung.—In October, 1951, Prof. A. Bradford Hill sent to each of the 59,600 members of the medical profession in the United Kingdom a questionnaire asking information about their smoking habits; 40,701 adequate replies were received. Since then, the registrar general has given Professor Hill details of every death of a physician. With Richard Doll (*Brit. M. J.* 2:1071, 1956), Hill has now analyzed the findings for the 53-month period from November, 1951, to March, 1956. During this period there were 1,854 deaths. Of these, 1,714 occurred in men 35 years of age and above. This group forms the basis for the authors' report. Of these 1,714 deaths, 81 were due to cancer of the lung.

The analysis shows a marked and steady increase in the death rate from cancer of the lung as the amount smoked increases. Thus, the annual death rate from cancer of the lung rises from 0.07 per 1,000 in nonsmokers to 0.47 per 1,000 in smokers of 1 to 14 gm. of tobacco a day (1 gm. is approximately equal to one cigarette), to 0.86 per 1,000 in smokers of 15 to 24 gm. of tobacco a day, and to 1.66 per 1,000 in smokers of 25 gm. or more of tobacco a day. In other words, the death rate of heavy smokers was about 20 times that of the nonsmokers. The rising mortality from cancer of the lung in smokers compared with nonsmokers and in heavy smokers compared with light smokers was observed in each of four age groups: 35-54, 55-64, 65-74, and over 75. The mortality from cancer of the lung was substantially and significantly greater in cigarette smokers than in pipe smokers. The annual death rate from this cause rose from 0.95 per 1,000 in smokers of 1 to 14 cigarettes a day to 1.67 per 1,000 in smokers of 15 to 24 cigarettes a day and to 2.76 per 1,000 in smokers of 25 or more cigarettes a day. The death rate of heavy smokers was about 40 times that of nonsmokers.

Evidence is produced suggesting that giving up smoking reduces the risk of dying of cancer of the lung. The annual death rate per 1,000 in those who had given up smoking for 10 or more years was 0.35, as compared with 0.59 in those who had given it up for less than 10 years and 1.03 in those who were still smoking. In other words, the mortality from this cause among current smokers was three times as great as that among men who had given up smoking for 10 or more years and 76% greater than that in men who had given it up within the previous 10 years. Since an analysis of a random sample of questionnaires showed that there was remarkably little difference between the smoking habits of physicians residing in Greater London, in large towns, and in other districts, it is concluded that the contrasts in lung cancer mortality between smokers and nonsmokers cannot be attributed to a differential exposure to atmospheric pollution that happens to be associated with smoking habits.

Study of the deaths from cancer in sites other than the lung did not reveal, other than for one possible exception, any association between mortality and smoking. The exception was cancer of the upper respiratory and digestive tracts, from which the number of deaths was insufficient to substantiate a possible trend. In total, mortality from cancer of sites other than the lung was 2.04 per 1,000 in nonsmokers and 2.02 per 1,000 in smokers. Mortality from coronary thrombosis showed a slight but significant relationship with smoking, but the trend was distinct only in the 35-to-54-years age group. Three other causes of death showed a steady increase in mortality from nonsmokers to heavy smokers: chronic bronchitis, peptic ulcer, and pulmonary tuberculosis, but only with chronic bronchitis was the increase significant, rising from 0.12 per 1,000 in nonsmokers to 0.72 in heavy smokers.

Smoking and Pulmonary Tuberculosis.—In the same issue of the *British Medical Journal* (page 1081), C. R. Lowe reports his findings in a group of 1,200 patients with respiratory tuberculosis. Among patients in both sexes of over 30 years of age with pulmonary tuberculosis there was a highly significant small number of nonsmokers and light smokers and a very large number of moderate and heavy smokers. The persons used by the author as controls came from certain sections of the local hospital population. He found that 11.7% of the tuberculous men were nonsmokers or had smoked less than 10 cigarettes a day as compared with 21% of the controls, while 50.1% of them had smoked 20 or more cigarettes a day as compared with 43.4% of the controls. From this he concludes that smoking may be an important cause of the breakdown of healed or quiescent respiratory tuberculosis in adults and may account for much of the excessive male mortality in middle and late life. This excessive mortality rate has become a marked feature in most large industrialized countries in recent years.

Increase in Scabies.—There has been a significant increase in the number of patients with scabies, according to Dr. F. F. Hellier, in the *British Medical Journal* (2:1117, 1956). A disturbing feature is the fact that in most cases the diagnosis is unsuspected by the general practitioner. Hellier, a dermatologist, suggests that 10 years of almost complete absence of scabies has tended to make older practitioners forget the diagnosis, while the new generation has not become familiar with it.

Faulty Feet.—Dr. I. Gordon, health officer for Ilford, reports that, of 1,400 school children between the ages of 9 and 10 years, drawn from all social levels, 468 had foot defects. Hallux valgus was more common among girls, accounting for 34% of all defects, compared with about 12% for boys. More girls had curled toes, presumably due to the wearing of tight shoes. The incidence of flat feet was equal in both sexes, but the number of boys with valgus ankles was double that found in girls. None of the children complained of pain in the feet or legs.

The "Open Door" in Mental Hospitals.—In his annual report for 1955, Dr. P. K. McCowan, the superintendent of Crichton Royal, Dumfries, one of the largest and oldest mental hospitals in the United Kingdom, reports that 6 of the 10 admission wards and 27 of the 31 long-stay wards in the hospital are now open. This means that 966 of the patients are in open wards and 266 in closed wards. Many of the patients in the closed wards are on parole, which means that it is only administrative necessity that prevents an even higher proportion of the patients from being in open wards. During the year, treatment with chlorpromazine and reserpine has continued to be tried out on an extensive scale, with very satisfactory results. In this period 16 standard leukotomies were performed. The results were in accordance with the hospital's last follow-up study, which showed that 34% of the patients undergoing leukotomy had been discharged socially recovered and that most of these were gainfully employed; a further 33% were much improved, although they still required hospitalization. The best results continue to be obtained in those whose preoperative personality was largely intact and who had well-adapted personalities before their breakdown. With few exceptions the patients operated on were those with schizophrenia who failed to respond to other methods of treatment and who were otherwise destined to spend the remainder of their lives as severe mental invalids. To date, 504 leukotomies have been performed on 450 patients, of whom 37 have had a second and 4 a third operation.

Tubercle Bacilli in Pasteurized Milk.—In Great Britain two main methods of pasteurizing milk are officially recognized. In the holding method the milk has to be retained at a temperature of not less than 145 F and not more than 150 F for at least 30 minutes and must be immediately cooled to a temperature of not more than 50 F. In the high-temperature short-time (H. T. S. T.) method the milk has to be retained at a temperature of not less than 161 F for at least 15 seconds and be immediately cooled to a temperature of not more than 50 F. In the holding method the milk is kept in a closed vessel during the whole time of its exposure to the prescribed temperature. In the H. T. S. T. method it flows continuously through a tube or a series of plates, which have to be adjusted so as to insure that every particle of milk receives the necessary amount of heat. During the years 1949 to 1952 an investigation was made by 22 public health laboratories in England and Wales concerning the presence of tubercle bacilli in milk pasteurized by these two methods. In the report of the investigation (*Month. Bull. Min. Health* 15:232, 1956) it is stated that, of the milk samples treated by the holding method, 8 of 201 giving a positive phosphatase reaction produced tuberculosis on injection into guinea pigs; none of the 524 giving a negative phosphatase reaction did so. Of the milk samples treated by the H. T. S. T. method, 2 of 93 phosphatase-positive samples produced tuberculosis in guinea pigs, but there was reason to believe that these 2 were raw milk samples used in error. Of 3,507 phosphatase-negative samples, one contained tubercle bacilli that were apparently derived from a filling machine used for tuberculous raw milk and one produced minimal lesions in the guinea pig. The lesions were reported at the time as being tuberculous, but the subsequent examination showed them to be almost certainly not due to the tubercle bacillus. As only a small proportion of phosphatase-negative milk samples were injected into guinea pigs, these figures cannot be used for calculating the real incidence of tubercle bacilli in pasteurized milk, but they can be used for comparing the efficacy of the two methods. They show that 8 of 725 (1.1%) samples treated by holding and one of 3,600 (0.03%) samples treated by the H. T. S. T. method contained tubercle bacilli. Although these results are taken to indicate that the H. T. S. T. method is the more satisfactory, it is noted that samples of milk reacting positively in the phosphatase test occur sufficiently often to justify more stringent control of processing, particularly of the smaller plants, by the sanitary authorities.

Psychosomatic Disease in General Practice.—Psychosomatic disease accounts for 15 to 20% of all the illnesses seen in an average practice in Great Britain, according to John Fry (*Practitioner* 177:554, 1956). In his own suburban practice of 5,000 patients, the most common psychosomatic disorders are hypertension (6%), migraine (2.8%), duodenal ulcer (2.5%) and asthma (1.3%). Other psychosomatic conditions treated included rheumatoid arthritis, fibrositis, ulcerative colitis, hay fever and vasomotor rhinitis, thyrotoxicosis, and menstrual and skin disorders. With the exception of hypertension, the incidence of which rises with age, and of asthma, which has its maximal incidence in childhood, most of these disorders occur in patients between 30 and 60 years of age. There is much sex variation. In the case of duodenal ulcer, men outnumber women 4 to 1, whereas in the case of hypertension, migraine, rheumatoid arthritis, and thyrotoxicosis, women outnumber men 4 to 1. The sex distribution is fairly equal in asthma, fibrositis, and the psychosomatic dermatoses. It is rare for a patient to suffer from more than one of these psychosomatic disorders at any one time. The only group of disorders to which some of these patients are prone are the effective neuroses; this is particularly evident in patients with migraine and duodenal ulcer. It is also unusual in the course of these disorders to find any sudden and obvious emotional stresses resulting in a consequent psychosomatic episode. It is much more usual to find that the summation of a series of hidden stresses is responsible.

In a seven-year period 36 of the author's 305 hypertensive patients, or 12%, died. In only 62 (20%), and this included many who subsequently died, were there any complications, and in only 35 (11%) were there any subjective symptoms related to complications. Of 145 patients treated for migraine 93 (63%) were well controlled, 42 (29%) were moderately well controlled, and in 11 (8%) there was failure to improve. Medical treatment kept 75% of the patients with duodenal ulcer relatively free from symptoms and at work. In the same seven-year period, of the 67 patients with asthma 2 died, 2 were severely disabled and unable to work, 8 were moderately disabled and required more-or-less continual therapy, and the remaining 55 (82%) were all leading normal lives with only occasional and minor episodes, which required either no specific treatment or merely ephedrine by mouth or inhaler.

CORRESPONDENCE

HYPERGLYCEMIA AND GLYCOSURIA FOLLOWING CHLORPROMAZINE THERAPY

To the Editor:—On the medical service of a large neuropsychiatric hospital, the following observations have been made during the past eight months in patients receiving chlorpromazine (Thorazine): 1. Five patients developed transient hyperglycemia and glycosuria, which disappeared upon cessation of drug use. 2. In five patients with previously controlled diabetes, the disease became unstabilized (higher blood sugar levels plus glycosuria) while they were receiving this agent. The condition of these patients reverted to prior status when chlorpromazine therapy was discontinued. 3. Two patients who had normal fasting blood sugar levels and negative urinalyses before drug therapy developed overt though mild diabetes mellitus during drug use; these conditions did not revert to normal when the drug was withheld. No present correlation has been made with the age of the patient, diagnosis, duration of hospitalization, sex, or dose or duration of chlorpromazine therapy. It is realized that this apparent relationship of chlorpromazine to a diabetic state may be fortuitous; such effects have apparently not been described previously, but their importance necessitates clarification of this possibility.

HOBBIES

To the Editor:—I am greatly interested in the Leisure Corner articles in The Journal, especially those that deal with the development of various hobbies to fill whatever minutes the busy physician can "steal" from his daily routine. I am one of those whose hobbies are collecting stamps and playing chess. I will deeply appreciate hearing from any accredited members of the American Medical Association who also collect stamps, with the end in view of corresponding and exchanging stamps with them.

CONGENITAL DEFECTS

To the Editor:—I certainly agree with Dr. Ingalls (*J.A.M.A.* 161:1047 [July 14] 1956) that "it is high time for orderly scientific methodologies to be used in the study of . . . congenital defects," but until the results of such studies are available for evaluation one cannot judge how far the findings of experimental teratology are applicable clinically. Dr. Ingalls has obtained evidence from experiments with mice that maternal hypoxia (or some related factor) can lead to developmental defects. From this he concludes that hypoxia is a "nonspecific stress." What exactly does he mean by "stress"? He goes on to say "Stress, of course, is to be defined more broadly than hypoxic stress" since other noxious agents such as x-rays, vitamin deficiencies, cortisone (and, he might have mentioned, genes) produce similar defects. Furthermore, he states, "a constellation of adverse maternal factors . . . anemia, hypothyroidism, organic heart disease, systemic hypertension, retroflexion, and tumor of the uterus" may affect the maternal organism in such a way that it triggers off "critical stress that leaves its impress on the conceptus for life," and, elsewhere, "The evidence is overwhelming that many, if not most, anomalous children have survived a temporary intrauterine stress" (in the summary the "many, if not most," changes to "most"). To paraphrase his argument—stresses are those factors that produce congenital defects. Therefore, congenital defects are caused by stresses. This is perfectly logical but does not improve our understanding of the causes of congenital defects. In order to prove that any given factor is teratogenic in humans one must begin by demonstrating either (1) that pregnancies exposed to the factor produce defective offspring more often than otherwise comparable pregnancies not exposed to the factor or (2) that the factor occurred in the pregnancies leading to defective offspring more often than in otherwise comparable pregnancies not leading to defective offspring. The only statistical evidence Dr. Ingalls quotes was obtained by the second method and concerns the prevalence of retroflexion of the uterus in 50 mothers of Mongoloid babies (24%), as compared to that in the mothers of a control group (8%). Here the difference between the two groups is not statistically significant, even at the 5% level, and hence may well be attributable to sampling error, rather than to any causal relationship. Although there is undoubtedly some truth in what Dr. Ingalls says, we have yet to find out how much. Until we have some solidly based clinical data, collected without bias, there is no justification for applying the findings of experimental teratology to humans.

STUDY OF SKELETONS

To the Editor:—J. Walter Wilson, M.D., in "Dividing Lines in Specialized Medical Practice" (*J. A. M. A.* 162:1025 [Nov. 10] 1956) states: "Studying bones recovered from early Stone Age strata, LeBaron found the skeletons of 18 men who had had fractured limbs, only 3 of which would be considered to have healed poorly, even by today's standards, thereby indicating that there were persons then living who had become expert at setting fractures." Although it is recognized that these statements are purely for background purposes in the development of his main topic, specialized medical practice, perhaps correction of two errors in the quotation above is worthwhile. First, LeBaron's study was concerned primarily with the neolithic rather than the paleolithic period (Palès, L.: Paléopathologie et pathologie comparative, Paris, Masson & Cie, 1930). Second, although granting that surgical skills had been developed in the neolithic period (e. g., trephining), the argument for this on the basis of position of healed fractures is not considered valid. Schultz has shown that well-healed fractures occur in significant proportions in wild anthropoids, among whom specialized medical skills are not highly developed (Schultz, A. H.: Notes on Diseases and Healed Fractures of Wild Apes and Their Bearing on Antiquity of Pathological Conditions in Man, *Bull. Hist. Med.* 7:571, 1939). This comment is submitted to clarify a statement made by Wilson in an otherwise excellent paper. It is hoped this observation will not be considered as mere academic sophistry.

MEDICAL AUDIT OF TESTIMONY GIVEN IN COURT

To the Editor:—Each county medical society should establish a medical audit of testimony given in court. This will give every testifying physician a score. Offenders with low score in honesty, integrity, and reliability of testimony can then be summoned before the executive committee and warned. If the practice of testifying "one way or the other" flagrantly persists, that physician should be dropped from the society. If he is a diplomate of any American board or college, this would really hurt. If not, the opposing lawyer could ask "Are you a member of your county medical society?" and "Why not?" I believe there is no need to explain at whom this is directed. It should clear the air around the courts; lawyers and the public would have more respect for the physician. Perhaps The Journal could circulate this need until it jells into concrete reality.

THE LEISURE CORNER

TIME OUT FOR CLOCKS

"Tick-tock" is a sound that masks ages of calculation; "ding-dong" is a sound that covers centuries of mechanical invention. The movement of the hands on the face of a clock, any clock, is a recording of infinity by man's measuring stick known as time. For time, says the philosopher, is a dimension. Astrophysicists now aver that the universe is in a state of constant change, reiterating the declamation of an ancient prophet, "A thousand years is but a day to God, and a day is a thousand years." We are told that if man could fly at a speed greater than light, he would be able to squat somewhere in space and see the construction of the pyramids.

Doctors who profess an interest in clocks enjoy their hobby without waiting for the coming of incredulous rates of speed and travel; indeed, they are unconcerned with machines that will measure the fourth dimension. These earth-bound, time-bound hobbyists enjoy clocks not only for their ability to keep accurate time but also for their intrinsic worth as decorative objects for the home.

An appreciation of old clocks usually comes naturally. A clock that holds considerable appeal for most collectors is the English clock, which has a twofold claim to recognition. First of all, if it be a fine old English clock, it will prove a reliable, accurate timekeeper. Secondly, clocks from certain periods are representative of styles of decoration now equaled but not surpassed by copyists. The English clock is actually a monument to a type of superb craftsmanship now almost extinct.

To set out to buy an old clock is for the beginner an experience akin to starting out to buy a horse. In the latter instance, a horse's teeth may be filed down and the hoofs pared to simulate equine youth. In an old clock, however, it is possible to add touches that will serve as a pretense for antiquity—a pair of old hands here, an antiquated-looking dial there, and an enshrining case of no particular period at all. Taken together, this could seem time's classic imprint of age. Then one might be induced to quote the Merchant of Venice, "I never knew so young a body with so old a head."

When one is contemplating the purchase of a clock, the case, the dial, and the hands should be studied very carefully. It is important to detect errors made by clumsy repairers and unskilled restorers who, often as not, have destroyed fine work. Moreover, there is the movement to be considered, the mechanism that makes a clock a truly worthwhile clock. These features are often overlooked by the average snapper-upper of old clocks or, when they are seen, not understood.

A clock is an ornament in a well-appointed home, whether it is located in the hallway, in the living room, or elsewhere. The contemporary collector wants a clock not so much because it is of ancient vintage but because he correctly assumes there are certain qualities represented in an old clock maker's art that are not to be found in later periods. A wise collector will not place himself in the hands of a dealer who has sold a thousand clocks, but in the hands of a practical clock maker, a trained artisan with a knowledge of old movements and one to whom clocks are more than inanimate objects. For him a clock is something with a soul.

Then there is the brass lantern clock, which usually appeals to the artist. In the famous painting "The Doctor," by Samuel Luke Fildes, there is a brass clock that adds a sense of immediacy to the emotional impact of the scene. The Old Masters frequently used brass clocks and candelabra to grace the paintings of interiors in the Low Countries. The reason for the name of the lantern clock may puzzle the contemporary collector. Its shape follows that of the lantern of the period in which the form was introduced, and it was made to hang on a wall. Form and usage determined its name, although, because it has spiked hooks to hang on, it is also known as a bracket clock.

The grandfather clock has no equal within its limits. It runs for eight days, and its construction is so lacking in mechanical guile that, when a repair job is required, a specialist need not be called. The grandfather clock has survived for two centuries or more as a standard English clock. The popular, endearing name suggests a certain amount of fascination for many people; indeed, it has been called the heritage of the poor, since it passes down from one generation to another. It is often cherished as an article of furniture and sometimes endowed with a value far greater than its actual worth.

The Shepherd or del Pastor, as it is known in Madrid, is one of the most celebrated clocks in the world. It has an automaton and an astronomical mechanism and apparently is the only clock known to possess such unusual functions. This clock indicates hours, minutes, and seconds, strikes hours, and repeats the hours, quarter-hours, and half-hours. The center of the dial presents the equation of time; a yearly calendar of the day, which corresponds to the length of each month; a calendar of the moon; signs of the Zodiac, which appear at the same time as the sun; the four seasons of the year; and an artificial solar dial, which indicates the hours by means of a visible shadow. Above the integrated center is a celestial vault, in which stars appear and disappear at the same time as seen in the heavens. The sun and the moon follow their respective courses according to the system of Ptolemy. This amazing clock displays the sun declining with the seasons. The moon in its different phases, despite its various positions, always appears illuminated on the side opposite the sun. When the weather turns rainy, the clock shows a cloudy sky covered with artificial clouds; these disappear the moment the sky clears.

Moreover, when the hour strikes, one hears a carillon of six airs, part of which are played as an echo. Stationed on a balcony is a lady, who is seated holding a book in her hand and beating time to the air that is played. She moves the book close to her eyes, takes a pinch of snuff several times, and bows gracefully whenever the glass covering of the clock is opened. After the carillon, a canary whistles six airs while moving its beak and body. The canary is perched on the fist of a Cupid, who by his gestures appears to be admiring the bird. Just as soon as this performance is terminated, a life-like shepherd, demonstrating tongue control and cadences, plays several airs on his flute. While this is going on, two Cupids balance themselves to the tune of the air being played. Although their movements are rotary, their stance remains upright. As a finishing touch to their performance, one of the Cupids falls over and, turning to the spectators, gestures to his friend as though to ridicule his own unsteadiness. All parts of the clock function separately without difficulty. These are the accomplishments of this famous clock that once won the admiration of the Spanish court.

The universally known cuckoo clock was first made by Anton Ketterer, of Schönwald in the Black Forest of Germany, in 1730. The charm exhibited by the cuckoo clock has captured the heart of many clock fanciers. Children especially love to watch the cuckoo bird call out the hour and the half-hour. Pediatricians have found that the younger generation will respond to the call of the cuckoo more readily than to "who's next please?" Sizes of the cuckoo clock vary, and cost depends on the carvings of the wood, the intricacies of the design, and, of course, the quality of the movement.

During the past few years the 400-day clock has become a favorite in many American homes. It is also known as an anniversary clock. During an annual celebration, held in Germany where these clocks are made, every owner winds his clock on the same day and follows this event up with social merriment. Hence, the name anniversary clock. Every month, hundreds of anniversary clocks are sent to this country as gifts. Today, it is estimated that there are over 2 million old and new 400-day or anniversary clocks in the United States alone, with more being shipped in every day.

Any clock that appeals to collectors, whether it is a hall clock, chime clock, water clock, or a banjo clock, has the potential value and interest that an antique would have. Imitation is the sincerest form of flattery. A thousand replicas usually start up a demand for a particular type of clock. The hobbyist of taste says that such and such a clock is unique in its artistic appeal to him. The collector with money purchases as many "uniques" and antiques as his distended bank account will encourage.

Several centuries ago Francis Bacon wrote, "If a man be in sickness or in pain the time will seem longer without a clock or hourglass than with it." It was once rare for a doctor to visit a sick patient and find a clock missing from the bedside. The clock frequently seemed to beat the very rhythm of life into the heart of the patient. Many patients became startled when the "tick-tock" of the clock ceased. The breath of life, they imagined, was sponsored by the rhythm of the bedside clock, and so small a detail as winding a clock made them aware that they were in full possession of their faculties.

"Doctors' Legacy"

Those who were interested in the article "The Doctor Writes a Letter" (Leisure Corner, *J.A.M.A.* 162:236 [Sept. 15] 1956) can find a detailed treatment in the book "Doctors' Legacy," the author of which is Dr. Laurence Farmer. This book was published by Harper & Brothers in 1955.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Medical Examiners: Can They Be Forced to Conduct an Inquest?—The medical examiner of Wayne County, Michigan, was directed by the county's prosecuting attorney to conduct an inquest in a particular case, as distinguished from an "investigation" provided in the act creating the office of medical examiner. A writ of prohibition was filed seeking to restrain the medical examiner from so doing and the case was heard in the Supreme Court of Michigan.

The question, said the court, is one of interpretation of act 181 of the Michigan laws of 1953. By Section 2 of this act the county medical examiner is obligated to make examinations upon the bodies of designated persons. By Section 5 his investigative procedures are, as the counsel for respondent say, "all spelled out." So far the act hints no duty or authority respecting the summoning of a jury and the holding of an inquisition according to time-honored practice. Section 7 provides that upon the written order of the prosecuting attorney or attorney general, or upon due filing of a petition signed by six electors of the county, the county medical examiner shall conduct an investigation according to the procedures set forth in Section 5. Section 13 then provides: "In counties having a medical examiner under the provisions of this act, the powers and duties vested by law in the office of coroner are hereby transferred to and vested in the county medical examiners and their deputies. In such counties immediately upon the taking effect of this act, the office of coroner shall be abolished, and whenever reference thereto is made in any law of this state, reference shall be deemed to be intended to be made to the medical examiners created by this act, insofar as consistent with the provisions of this act. Any hearing or other proceeding pending before any coroner shall not be abated but shall be deemed to be transferred to the medical examiner of the proper county and shall be conducted and determined by such examiner in accordance with the provisions of law."

The prosecutor contended that all of the previously known powers and duties of coroners, including the power and duty of jury inquisition and functions thereof, were transferred by this section to the county medical examiner. The respondent says that on the strength of the words "insofar as consistent with the provisions of this act" the power and duty of coroner-jury inquisition was not so transferred.

The purpose of the medical examiner act, said the Supreme Court of Michigan, was to eliminate the senescent "crowner's quest" in counties where the electorate decided by the terms of the 1953 act to accept the principle of pathological investigation in lieu of coroner-jury inquisition. We find that the legislature intended that the act extends investigative power only, as defined in sections 1 through 12, to the medical examiner of Wayne County. As was said in a New York decision, "The chief medical examiner acts without a jury, holds no inquest, renders no decision, holds no one to answer, issues no warrant of arrest. The ancient office is gone and the ancient duties have largely disappeared with it. Another method of investigating suspicious deaths has supplanted crowner's quest."

Accordingly the Supreme Court approved an order restraining the medical examiner from summoning a jury and conducting an inquest in the case in question. *Lipiec v. Zawadski and O'Brien, 77 N. W. (2d) 763 (Mich., 1956).*

Right of Unlicensed Person to Use "M.D." Degree.—The plaintiff filed a petition against the Board of Medical Examiners to enjoin it from prosecuting him for alleged statutory violations. From an adverse judgment by the district court, the plaintiff appealed to the district court of appeals, second district, division 2, California.

The plaintiff graduated from a medical school in Ohio and practiced medicine in that state for a number of years. He then moved to California and founded the Lawton School for Medical Assistants. In certain advertising material in connection with this school, the plaintiff used his name, followed by the letters "M.D." The defendant board contended that such action was a violation of Section 2142 of the California law that provides: "Any person, who uses in any sign, business card, letterhead, or in an advertisement the word 'doctor,' the letters or prefix 'Dr.,' the letters 'M.D.' or any other term or letters indicating or implying that he is a physician and surgeon, physician, surgeon or practitioner under the terms of this or any other law, or that he is entitled to practice hereunder, or under any other law, without having at the time of so doing a valid, unrevoked certificate as provided in this chapter, is guilty of a misdemeanor."

The plaintiff first contended that because he was not engaged in the practice of medicine, the section could not in reason apply to him and that the section was therefore unconstitutional as to him because it deprived him of a valuable property right, to wit, the right to the use of the letters "M.D." to indicate the area of his professional training.

Conceding, *arguendo*, that the plaintiff has a property right in the significant letters, said the court, still it must be acknowledged that such right does not take precedence over the public welfare that the section seeks to conserve. It is apparent that the legislature may well have deemed it wise that those who instruct in the science of medicine should be forced to disclose their educational backgrounds and that they should not be allowed to mislead students into thinking their instructors are licensed to practice medicine in California. If in fact the teachers have had excellent medical training, there is nothing in the law that prevents them from indicating such fact. Medical schools do not uphold equally the same high standards, nor does California maintain reciprocity in the medical field with all other states. The student and the public are entitled to know the qualifications of those who directly or indirectly affect the public welfare as does the medical profession. Neither graduation from a reputable institution nor want of sufficient education will excuse the necessity of being certified before a person may advertise his right to adorn his name with Dr. or M.D. Such letters are false insignia when a physician attempts to tell the world he is licensed when in fact he is not. Whether they actually practice here is immaterial. The intent of the legislature was to shield the public against those who for any reason have not been duly licensed. The plaintiff's offense, said the court, was in holding himself out as a physician in this state although he does not possess a valid license to do so.

The plaintiff also contended that the section could not be justified under the police power because it had no relation to the public health or safety as applied to him. A person in California who holds himself out to the public as a licensed physician and purports to teach here the science of medicine and the art of its practice to students to enable them to pass California examinations, said the court, is clearly liable under the section and the public is aggrieved by his representing himself in the manner forbidden by the statute. The legislature intended every person engaged in professional activities properly to represent himself in his true capacity by appropriate title.

Other contentions of the plaintiff were also overruled and the plaintiff's request was denied. Judgment for the defendant Board of Medical Examiners was affirmed. *Lawton v. Board of Medical Examiners, 299 P. (2d) 362 (Calif., 1956).*

ILLUSTRATED FILM REVIEWS

Illustrated reviews of current films will appear when possible as a regular feature in The Journal. *They will consist of an introduction by the author followed by a pictorial digest of actual frame enlargements selected as key points of the film. This type of review should enable clear visualization of the author's treatment or technique.*

The first few illustrated reviews will be based on films for which a regular review has already been published; however, it is planned in the future to publish both the illustrated and printed review of current films in the same issue.

Ralph P. Creer, *Director Motion Pictures and Medical Television, Council on Scientific Assembly*

SURGICAL TREATMENT OF DISSECTING ANEURYSM

Michael E. De Bakey, M.D., Denton A. Cooley, M.D.
and
Oscar Creech Jr., M.D., Houston, Texas

Dissecting aneurysm of the aorta is associated with a grave prognosis, but recently a method has been developed that seems to offer an effective surgical approach to the problem. The underlying predominant lesion is degeneration of the elements of the media. The dissection commonly begins as a transverse tear in the intima and media in the ascending aorta or descending limb of the aortic arch near the origin of the left subclavian artery. Separation of the intramural layers of the aorta by the forceful stream of blood produces dissection involving all or a portion of the circumference of the aorta. Surgical treatment is directed toward correction of the dissecting process by removal and repair or interruption of its progress by creation of conditions compatible with function and eventual repair. One of two methods may be used, the first when the dissection originates in the ascending aorta and the second when it begins near the origin of the left subclavian artery. This method has been successful in 14 of 18 cases, with an operative mortality of 22%. Follow-up over two years indicates highly gratifying results. (This film was reviewed in The Journal, Nov. 10, page 1078.)

Fig 21 —Anastomosis of aortic homograft has been completed and occluding clamps removed, permitting restoration of normal aortic lumen

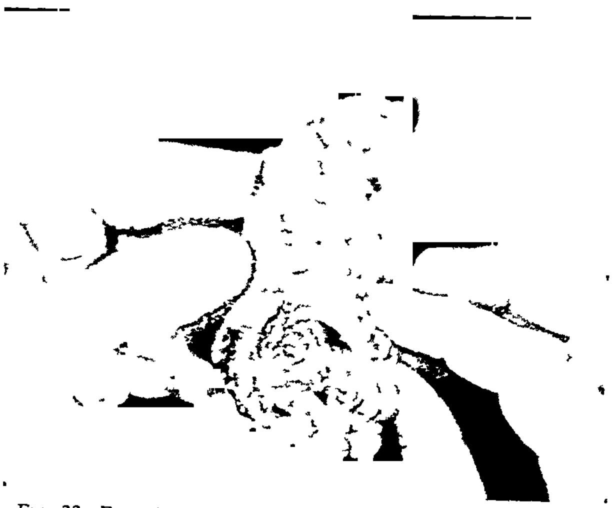

Fig 22 —Excised segment of aorta showing normal lumen markedly compressed by dissecting aneurysmal process containing partially organized thrombus

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Influence of Hot and Humid Environment on the Patient with Coronary Heart Disease. G. E. Burch. J. Chron. Dis. 4:350-363 (Oct.) 1956 [St. Louis].

That a hot and humid environment may be dangerous is evident from experiences in communities suddenly struck by a heat wave, when people of the older age groups and those with degenerative diseases are especially prone to succumb. The author reviews observations he made in studies carried out over a number of years on the influences of a hot and humid environment on the cardiovascular system. He emphasizes that such an environment can increase cardiac work as much as strenuous physical exercise. The hot and humid environment produced by climate, industrial working conditions, or overcrowding of the sickroom must be considered in the treatment of all patients in whom it is desired to reduce cardiac work. Greater use of air-conditioning in hospitals, cardiac wards, offices, and homes will assist toward this end. Many important problems concerning the influence of the hot and humid environment upon man remain unsolved and should be studied.

Acute Coronary Insufficiency: Its Differential Diagnosis and Treatment. A. M. Master, H. L. Jaffe, L. E. Field and E. Donoso. Ann. Int. Med. 45:561-581 (Oct.) 1956 [Lancaster, Pa.]

Acute coronary insufficiency is a specific clinical, electrocardiographic, and pathological entity differing from both angina pectoris and acute coronary occlusion. It indicates a more prolonged and severe myocardial ischemia than does "angina," yet does not present the characteristic electrocardiographic and laboratory features of major infarction secondary to coronary occlusion. There is no change in the heart sounds; there is no pericardial rub, heart failure, or peripheral embolization. In coronary insufficiency mild fever, slight leukocytosis, and a slight increase in sedimentation rate may appear, if significant subendocardial necrosis results. No acute thrombus is present in the coronary arteries at autopsy. The incidence of "acute coronary insufficiency" is much greater than that of coronary thrombosis. Since an attack of "acute coronary insufficiency" is rarely fatal, postmortem studies and statistics to determine its frequency are not reliable. The pathological studies that are available, particularly among Armed Forces personnel and in cases of "sudden death" in civilians, indicate that myocardial infarction occurs not infrequently without any thrombosis, i. e., as the result of "acute coronary insufficiency." Estimating that one million attacks of coronary thrombosis occur annually in the United States, the authors regard it as probable that at least 1.5 to 2 million attacks of "acute coronary insufficiency" occur each year.

Acute coronary insufficiency can develop spontaneously. Often it follows severe hemorrhage, tachycardia, marked physical exertion, emotional upset, trauma (surgical or accidental), sudden hypertension, shock, pulmonary embolism and infarction, severe infection, and heart failure. Such cases should be termed "acute coronary insufficiency" secondary to whatever the causative condition may be. Prompt treatment of the precipitating factor may terminate the resultant coronary insufficiency and may even prevent it. In acute hemorrhage, replacement of blood may be life-saving, as are vasopressor drugs in shock and hypotension. The termination of severe tachycardia is also vital. The presence of a precipitating factor in a coronary episode suggests the presence of coronary insufficiency rather than occlusion. When coronary insufficiency occurs spontaneously, it may clinically resemble coronary occlusion with mild manifestations. The electrocardiographic picture usually serves to distinguish them. The treatment of coronary insufficiency and coronary occlusion differs; hence, the recognition of the former as an entity is essential. In uncomplicated coronary insufficiency, the authors employ rest for a period of usually only one to two weeks, avoiding protracted immobilization with the accompanying hazards of peripheral thrombosis. Most patients recover and resume work within several weeks. Mural thrombi do not occur in coronary insufficiency; hence, anticoagulants need not be administered.

Influence of Oxygen Inhalation on Renal Function in Patients with Cardiac Decompensation. M. Földi, F. Soliti, E. Koltay and others. Klin. Wchnschr. 34:857-859 (Aug. 15) 1956 (In German) [Berlin, Germany].

The authors investigated the effect of oxygen inhalation on renal function in patients with cardiac decompensation. Glomerular filtration was determined with the aid of endogenic creatinine clearance; the effective quantity of plasma circulating through the kidneys was ascertained by means of PAH (*p*-aminohippuric acid) clearance; sodium was estimated with a flame photometer; and oxygen saturation of the blood was ascertained photoelectrically. After three control clearance periods (duration of a clearance period was 10 minutes) the patients inhaled for 30 minutes an oxygen–carbon dioxide-nitrogen mixture that provided 50% oxygen and 4% carbon dioxide. After this, three more clearance periods were recorded. The tests revealed that the circulatory insufficiency of cardiac decompensation is essentially due to a chronic hypoxia. This chronic hypoxia changes the renal function in the healthy organism in a manner that is identical with the renal function during cardiac decompensation. As the hypoxia is counteracted in patients with cardiac decompensation, the renal function becomes normalized, thus proving the theory that functional disturbances in the kidneys of patients with cardiac decompensation are caused by hypoxia.

Diagnostics and Therapy of Infections with Brucella Abortus and Brucella Melitensis in Man. H. Winter, W. Schmidt, G. Huels and D. Strauch. Medizinische, No. 40, pp. 1430-1434 (Oct. 6) 1956 (In German) [Stuttgart, Germany].

Thirty-seven patients with brucellosis caused by Brucella abortus and 17 patients with brucellosis caused by B. melitensis were treated with antibiotics at the medical clinic of the Justus Liebig-University of Giessen, Germany. The 54 patients, most of whom were farmers and some veterinarians, were followed up for from one to six years after their discharge from the hospital. Treatment consisted of administration of broad-spectrum antibiotics, i. e., chlortetracycline (Aureomycin), tetracycline, and oxytetracycline (Terramycin) with an initial daily dose of 2 gm., which later was reduced to 1.5 or 1 gm. A total dose of 30 gm. was given in the course of from two and a half to three weeks. Antibiotic therapy was combined recently with the administration of "stress fortification" vitamins. Erythromycin was given to two patients but was withdrawn because of its limited effect. Chloramphenicol was not used. Six of the 17 patients with brucellosis caused by B. melitensis received only broad-spectrum antibiotics, and 11 were given broad-spectrum antibiotics combined with streptomycin. A total dose of 15 gm. of streptomycin was given. Recurrences with fever were observed in 2 of the 6 patients and in 5 of the 11 patients. The recurrence ratio thus was the same in both groups. Combined antibiotic therapy thus did not prove superior to treatment with broad-spectrum antibiotics alone, which was practiced in the

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

37 patients with brucellosis caused by B. abortus. Two of these patients had recurrences. The relapses occurred within a few weeks after antibiotic therapy was discontinued.

Broad-spectrum-antibiotic therapy is the method of choice for the treatment of brucellosis. The temperature is restored to normal within four or five days. The permanent success of the treatment depends on its early institution. Complete recovery, however, may be obtained only in 20 or 30% of the patients even if the treatment is instituted within the first eight weeks after the infection. Results of treatment are even less satisfactory in patients with chronic brucellosis, and it may be difficult to draw the line between recoveries resulting from treatment and tendencies to spontaneous recovery. The source of infection as a rule does not permit definite conclusions concerning the type of the Brucella infection. Cattle may serve as source of infection caused by B. melitensis, and sheep may transmit infection caused by B. abortus. Only the results of blood culture and quantitative agglutinin saturation can prove the character of the infection. This proof was obtained in 9 of the 17 patients with brucellosis caused by B. melitensis.

Histoplasmosis Contracted in Britain: A Case of Histoplasmic Lymphadenitis Following Clinical Recovery from Sarcoidosis. W. S. C. Symmers. Brit. M. J. 2:786-790 (Oct. 6) 1956 [London, England].

The author describes a case of histoplasmosis in a 46-year-old man who had never been out of the British Isles before the development of the disease. The only manifestations of the infection were the enlargement of two cervical lymph nodes and a positive skin reaction to histoplasmin. Fungi were found in sections of one of the lymph nodes. The diagnosis was established by the isolation of Histoplasma capsulatum in cultures from one node. The patient was without symptoms when last heard from, 16 months after the mycotic lymphadenitis appeared.

The patient's case is believed to be the first unequivocal instance of mycologically proved histoplasmosis in which the infection was contracted in Britain. History revealed that he had previously had sarcoidosis, the course of which was benign. At the age of 27 years he fell and cut his forehead on a path of splintered flint. The wound healed rapidly without suturing. Fourteen years later the scar became livid and indurated, forming a slowly growing, smooth linear swelling. It was excised, and sections showed a typical siliceous granuloma formed by tubercle-like structures of sarcoid type. All the manifestation of this initial illness had disappeared a year before the histoplasmic lymphadenitis developed. There is no reason to presume any relationship between the old injury in this case and the eventual occurrence of the fungal infection. It is unlikely that the original illness, believed to be sarcoidosis, was a manifestation of histoplasmosis. The absence of symptoms, the apparently complete recovery, the character of the radiological changes in the lungs and their disappearance without calcification, the clear-cut microscopic picture of sarcoidosis, and the failure to find parasites in the original biopsy specimen and in the siliceous granuloma were all features that favored the diagnosis of sarcoidosis.

Development of Resistance by Tubercle Bacteria to Various Chemotherapeutics in Combination. S. Winblad. Acta tuberc. scandinav. 32:118-131 (No. 2) 1956 (In English) [Copenhagen, Denmark].

Tubercle bacilli obtained from 865 patients with pulmonary tuberculosis who were treated at the chest clinic of the General Hospital in Malmö, Sweden, were studied systematically with regard to the development of resistance to streptomycin, isoniazid, and aminosalicylic acid. The tubercle bacilli were inoculated into Löwenstein-Jensen's medium to which varying doses of the chemotherapeutic agents had been added. The total doses of the chemotherapeutic agents that had been administered to the patients were taken into account, and so was the duration of the streptomycin and/or isoniazid therapy, which was combined with the administration of aminosalicylic acid in all the patients. Results showed that when the total dose of streptomycin exceeded 90 gm. after daily administration, more than 80% of the surviving bacteria had developed resistance to streptomycin. In a smaller group of patients who had received the same total dose of streptomycin by intermittent administration, the resulting incidence of resistance was the same. Combined treatment with streptomycin and isoniazid reduced the incidence of streptomycin-resistant strains. In patients treated with isoniazid not combined with streptomycin, the resistance of the bacteria to isoniazid was appreciable after four months of treatment. Combined treatment with streptomycin reduced the incidence of isoniazid-resistance among the surviving bacterial strains. Not until aminosalicylic acid had been administered for more than three years did the resistance of the tubercle bacilli to aminosalicylic acid become clinically important.

Tuberculous Meningitis: Combined Corticosteroid and Antimicrobial Therapy. S. J. Shane, S. E. Copp and T. K. Krzyski. Canad. M. A. J. 75:631-634 (Oct. 15) 1956 [Toronto, Canada].

Thirty patients with tuberculous meningitis were given combined treatment with streptomycin, aminosalicylic, and corticosteroid preparations at the Point Edward Hospital in Sydney, Nova Scotia, and in three other hospitals between 1953 and 1955. Hydrocortisone in an initial daily dose of 200 mg. was used as the corticosteroid of choice, rather than cortisone in an initial daily dose of 300 mg. Twenty-five patients made a complete recovery and five died. One of the five patients who died had a complete infarction of the right cerebral hemisphere that appeared to preclude recovery by any form of treatment. Two additional patients who failed to recover were admitted to hospital in so late a stage of their disease that no method of treatment could have been expected to bring about a satisfactory result. If one excludes these three patients, there remain 27 treated, 25 of whom recovered, i. e., a recovery rate of 92.6%. This recovery rate represents a distinct improvement over that in previous and current reports in the literature. Five of the 25 patients who recovered were comatose or their conditions were deteriorating or stationary when treated with streptomycin, aminosalicylic acid, and isoniazid. Dramatic clinical and laboratory evidence of improvement was noted in these patients shortly after corticosteroids were added to their therapeutic regimens.

It would seem to be clear that the addition of corticosteroids to antimicrobic regimens including isoniazid in patients with tuberculous meningitis is capable of bringing about striking improvement when the previous condition has been unsatisfactory. Neurological sequelae were distinctly less frequent in corticosteroid-treated patients than in others. There was no evidence of exacerbation of nonmeningeal tuberculosis or any evidence of the occurrence of significant intercurrent nontuberculous infections resulting from the use of corticosteroids in this disease. The corticosteroid-antimicrobic regimen in patients with tuberculous meningitis thus has advantages over antimicrobic therapy alone, even when such antimicrobic therapy includes isoniazid.

Some Quantitative Aspects of Treatment with Quinidine. M. Sokolow. Ann. Int. Med. 45:582-588 (Oct.) 1956 [Lancaster, Pa.]

The customary reliance on quinidine dosage is less satisfactory than the determination of the concentration of quinidine in the blood. Quinidine can be determined in the blood because it fluoresces in acid media, and the degree of this fluorescence can be measured in a Coleman fluorometer. Serum concentration of quinidine determines both the conversion of an arrhythmia as well as toxicity. Toxic reactions rarely result from true sensitivity or idiosyncrasy manifested by fever, purpura, rashes, or hypotension. A test dose of 0.2 gm. of quinidine is advisable before starting treatment, in order to determine possible idiosyncrasy. Other signs of mild or moderate quinidine intoxication consisting chiefly of nausea, diarrhea, and occasionally of headache or tinnitus rarely require the cessation of treatment with quinidine. The gastrointestinal disorder can be controlled by sedatives, paregoric, or thorazine. When signs of myocardial intoxication are present, such as frequent ventricular premature beats (one or more every six beats), an increase of QRS width of 50% or more, complete AV block, ventricular tachycardia, or ventricular fibrillation, the author usually discontinues treatment with quinidine. In about

700 serum determinations it was found that only three cases of myocardial toxic reaction had occurred at serum levels less than 6 mcg. per milliliter, and none at less than 3 mcg. per milliliter. The incidence of myocardial toxicity increased progressively as the serum concentration exceeded 6 mcg. per milliliter; it rose to 65% at levels over 14 mcg.

The conversion of chronic auricular fibrillation to sinus rhythm by the use of quinidine was studied in 214 conversion attempts in 177 patients. Conversion was attempted by one of two techniques: (1) the rapid method—0.4 gm. every two hours for five doses, repeated the next day, then increased to 0.6 gm. every two hours for five doses if warranted by the patient's response and the absence of toxic reaction; and (2) the slow method—0.4 gm. four times a day for 72 hours, increased to 0.6 gm. four times a day for 72 hours, and then to 0.8 gm., depending upon the response and lack of toxic effect. Factors having an adverse effect on conversion were rheumatic etiology; duration of fibrillation longer than six months, and especially longer than a year; the presence of cardiac failure that did not respond to the usual measures of therapy; and mitral insufficiency. The conversion rate was approximately 75%, but it varied from 95% in patients without cardiac failure and with fibrillation of short duration to approximately 45% in patients with mitral regurgitation, with or without cardiac failure. Determination of quinidine concentration in the serum should decrease the risk of toxicity to the patient and permit safer and more effective therapy.

Treatment of Acute Pancreatitis with Cortisone. N. C. Rogers, A. O. Wilson, M. J. Meynell and W. T. Cooke. Lancet 2:651-652 (Sept. 29) 1956 [London, England].

The authors present observations on six patients with acute pancreatitis who were given cortisone in addition to the usual supportive measures. All recovered. The authors gained the impression that cortisone therapy favorably influenced the rate of recovery. The patients who were operated on were usually given an intramuscular injection of hydrocortisone after the operation, and, thereafter, prednisone was given by mouth in addition to antibiotics, fluids intravenously, and other measures. Patients not operated on were given prednisone by mouth together with other treatment. Two of the six patients had especially severe forms of pancreatitis. The authors feel that these two probably would have died without the use of cortisone, the more so since they had observed four successive deaths from necrosis of the pancreas before they resorted to the use of cortisone.

Gamma Globulin Deficiency: Report of a Case and Survey of Literature. A. H. Greenhouse. J. Kansas M. Soc. 57:611-618 (Oct.) 1956 [Topeka, Kan.].

The patient was a 58-year-old man recently observed at the University of Kansas Medical Center. He had repeated bouts of fever. Electrophoretic studies of his blood failed to show the presence of gamma globulin. Hematological studies did not reveal isohemagglutinins. Typhoid immunization was attempted, and he responded to each injection with a marked temperature spike, but repeated studies failed to reveal any agglutinins to typhoid. The patient was febrile during the early part of his hospital stay until he was given an injection of 20 cc. of gamma globulin, at which time his temperature subsided almost dramatically. He remained afebrile except for the temperature elevations with typhoid immunization and felt well on discharge from the hospital. Since then he has been followed in the Kansas University Medical Center outpatient clinic and has had a few febrile bouts, each of which responded promptly to gamma globulin injections.

The literature on agammaglobulinemia suggests that it is probably not a rare condition. The following features should raise the suspicion of agammaglobulinemia: (1) grossly inadequate resistance to infection, as manifested by frequently recurring and unusually severe infections; (2) failure to develop clinical immunity after a seemingly adequate antigenic stimulus, such as repeated attacks of a disease usually conferring permanent immunity; and (3) certain laboratory findings. Treatment consists of replacement of gamma globulin.

Urinary Gonadotrophin Excretion in Osteoarthritis. F. B. Rogers. Am. J. M. Sc. 232:419-420 (Oct.) 1956 [Philadelphia].

The authors observed a patient with arthritis mutilans, in whom the cartilaginous lesions had repeatedly flared up after the injudicious administration of chorionic gonadotropins. Since cartilage destruction occurs in both osteoarthritis and arthritis mutilans, it seemed worthwhile to find whether osteoarthritic patients showed excess gonadotropin excretion. Ten postmenopausal patients were selected who had osteoarthritis involving the proximal and distal interphalangeal and other joints. Pituitary gonadotropin excretion was almost identical in the 10 patients with osteoarthritis and in 10 matched controls. It may, therefore, be assumed that the amount of gonadotropins, as measured by current techniques, is not a factor in the causation of osteoarthritis.

Staphylococcal Gastroenteritis: Report of a Major Outbreak. H. Wain and P. A. Blackstone. Am. J. Digest. Dis. 1:424-429 (Oct.) 1956 [New York].

Symptoms of food poisoning appeared in 244 of 306 persons attending a picnic. The offending food was baked ham from which cultures of Micrococcus (Staphylococcus) aureus were obtained by two separate laboratories. The baked ham presented no off-odors, tastes, or flavors. This is characteristic of foods infected with micrococci. It was established that the baked ham was seeded with M. aureus from the self-contaminated hands of the man who did the deboning. Laboratory cultures demonstrated M. aureus in acne lesions on the man's face, in the ham, and in scrapings taken from the table on which the hams were deboned. The micrococci organisms were given the necessary time and temperature range in which to grow and produce enterotoxin in the sliced ham during the period that the hams were held warm in the oven at 200 F. Additional growth and enterotoxin production occurred during the period that the hams were held without refrigeration at the picnic grounds, on a day when the temperature was 90 F. The characteristic feature of micrococcic gastroenteritis is the relatively short incubation period, which is usually one to six hours. This is in contrast to incubation periods of 12 to 24 hours or more in botulism or poisoning due to Salmonella. This point is of importance in diagnosis, both clinically and epidemiologically, because if the incubation period is longer than 11 hours, micrococcic gastroenteritis can be ruled out.

The majority of the patients recovered in from 24 to 72 hours. Several patients were hospitalized as long as five days. One individual who had a long history of ulcerative colitis had severe bleeding from the mouth and anus and needed 2 pt. of blood. It is important that all food handlers receive a daily inspection and that no employe be permitted to come in contact with food who has an uncovered open sore or obvious infection. This outbreak could have been prevented had this been done. However, because of the ubiquity of carriers of Micrococcus organisms and the impracticability of eliminating them from food handling, all foods must be properly handled and stored. Food must be kept constantly hot, properly refrigerated, or promptly eaten. Reheating of food requires at least 30 minutes at 350 F to effectively inactivate any enterotoxin that may have contaminated it.

Hodgkin's Disease and Caseous Tuberculosis (With Report of a Case). E. H. Horton. Brit. J. Tuberc. 50:365-367 (Oct.) 1956 [London, England].

Horton reports on a 56-year-old woman with enlarged left supraclavicular lymph nodes. One of these was excised, and biopsy showed caseous tuberculosis. She was treated with streptomycin and isonicotinic acid hydrazide but failed to improve and soon became wasted and anemic. She also had symptoms of an abdominal nature, and marked enlargement of liver and spleen was noted. Death ultimately occurred from hepatic failure thought to be due to tuberculous involvment of the liver. Diagnosis of Hodgkin's disease was not made in this case until death had occurred. It had been considered in differential diagnosis, but the discovery of caseous tuberculous lesions in the cervical lymph node biopsy was always the overriding consideration. Also, the high alkaline phosphatase value recorded at one stage of the illness suggested the possibility of biliary obstruction caused by enlarged tuberculous lymph nodes in the portal fissure. At autopsy the hepatic enlargement was found to be due to Hodgkin's disease. Microscopic examination of the enlarged cervical nodes showed the classic picture of Hodgkin's infiltration on the one hand and caseous tuberculosis on the other. Different areas of the same lymph node exhibited this feature. No tubercle bacilli were demonstrated. This case illustrates the extremely close relationship that exists between these two conditions. If this had been appreciated, the true nature of the condition that ultimately caused death might well have been realized during the course of the illness by further microscopic examination of the cervical lymph nodes. In the light of the clinical course, too much significance was attached to the single biopsy report.

The Long-Term Results of the Treatment of Pulmonary Tuberculosis by Pneumoperitoneum. A. Pines. Brit. J. Tuberc. 50:338-345 (Oct.) 1956 [London, England].

A follow-up of at least six and a half years was deemed necessary to evaluate the long-term results of pneumoperitoneum in the treatment of tuberculosis. The years chosen for analysis, therefore, were 1945 to 1947, when pneumoperitoneum was in maximal use at the author's (Harefield) hospital. Streptomycin was not used initially in any of these patients and in comparatively few during after-years. All patients who received primary pneumoperitoneum treatment were included and also those in whom a pneumothorax had been tried but had failed and had been promptly abandoned. The pneumoperitoneum had been maintained in all of these patients for at least three months. Of 334 patients who had been treated with pneumoperitoneum, 287 could be traced; in 225 adequate data were available. Fifty-nine (26%) of the patients had died by the end of the observation period. In relation to extent of disease, 17% of those who had moderately advanced disease died, as did 57% of those who had far-advanced lesions. These results were compared with the published results in patients treated largely by bed rest alone in relation to comparable extents of disease. There was little or no significant difference in their ultimate fate. Pneumoperitoneum treatment, therefore, had little demonstrable effect upon survival in this series of patients. It is not, consequently, a primary treatment of value in pulmonary tuberculosis.

The Efficacy of BCG Vaccination: Epidemic of Tuberculosis in a State School, with an Observation Period of 12 Years. T. V. Hyge. Acta tuberc. scandinav. 32:89-107 (No. 2) 1956 (In English) [Copenhagen, Denmark].

An epidemic of tuberculosis occurred in a Danish State school for girls in the first three months of 1943. This epidemic fulfilled most of the requirements of a controlled experiment concerning BCG vaccination. The 368 girls who attended the school at the time of the epidemic were followed up for more than 12 years. At the annual examination for tuberculosis in December, 1942, which preceded the outbreak of the epidemic, Mantoux tuberculin tests were performed on 368 girls; 105 had a negative reaction to the test, 133 had a positive reaction after BCG vaccination, and 130 had a spontaneous positive reaction. Thus 263 girls were tuberculin-positive. Most of the tuberculin-negative pupils were newcomers to the school, and it was not possible to have them vaccinated before the outbreak of the epidemic. Ninety-four of the 105 girls were exposed to the infection. Seventy of the 94 turned from tuberculin-negative to tuberculin-positive. Forty-one convertors showed evidence of primary tuberculosis. Postprimary progressive pulmonary tuberculosis occurred in 14 convertors (15% of the 94 exposed girls) after a latent period of up to 10 years. Of the 133 BCG-vaccinated girls, 106 were exposed to the infection under the same conditions as the tuberculin-negative girls. None of these showed evidence of primary tuberculosis, and postprimary progressive pulmonary tuberculosis occurred in only two (1.9% of the exposed). There were, therefore, eight times as many cases of postprimary pulmonary tuberculosis in the tuberculin-negative group as in the BCG-vaccinated group; the total incidence of primary and postprimary tuberculosis was 23 times as high among the tuberculin-negative as among the BCG-vaccinated pupils. Of the 130 pupils with a spontaneous positive reaction to tuberculin, 105 were exposed to the infection: progressive pulmonary tuberculosis occurred in 10 of the 105 after a latent period of up to more than eight years.

Twenty-four cases of postprimary progressive pulmonary tuberculosis thus occurred in the initially tuberculin-negative and tuberculin-positive groups as compared with only two cases in the BCG-vaccinated group. It is evident that the person most effectively protected against tuberculous infection is the non-reactor who is properly vaccinated with a potent BCG vaccine that produces strong and lasting allergy.

Considerations on 53 Cases of Malignant Lymphogranulomatosis with Attention to Tubercular Reactions of the Skin. A. Zurlo and G. Greco. Sett. Med. 44:375-380 (July 31) 1956 (In Italian) [Florence, Italy].

The authors report on 53 patients with malignant lymphogranulomatosis, as ascertained by biopsy. There were 34 males and 19 females. Their ages ranged between 11 and 67 years. The symptoms had been present for from one month to 11 years. Eleven of the 53 patients returned two, three, or four times for observation during relapses. Twenty-two patients presented a positive Mantoux test. Seven of these had had tuberculosis and two had relatives with tuberculosis. The initial localization of the disease was most frequently in the lateral cervical regions (28 of 53 patients). Other locations were mediastinum, 58 patients; supraclavicular region, 3 patients; axillary region, 5 patients; and inguinal region, 3 patients. The number of leukocytes in peripheral circulation was above 8,000 per cubic millimeter. Eight patients who had had the disease for four months or less had a leukocyte count of 8,737 per cubic millimeter. Neutrophilia and lymphocytopenia were present in 27 patients (50.94%). Eosinophilia with values higher than normal was present in 13 patients (24.52%). Marked splenomegaly was present in 14 patients (26.41%). Itching was present at the beginning in only 12 patients (22.64%). Apparently there was no relationship between itching and tuberculin intradermal reaction. High fever was present in 20 patients (37.73%), all of whom had had the disease for at least a year; low fever was present in 24 patients (45.28%). Nine patients had no fever when they entered the hospital. The authors conclude that a positive Mantoux test in patients with lymphogranulomatosis depends upon previous tuberculous infection and on the condition of the patient during the initial stage of the disease, when the reactivity of the tissues is still present.

The Treatment and Prognosis of Hepatic Coma. S. Sherlock, W. H. J. Summerskill and A. M. Dawson. Lancet 2:689-694 (Oct. 6) 1956 [London, England].

The authors report observations on the treatment of 66 consecutive patients (41 females and 25 males) with liver disease complicated by hepatic coma or precoma. Diagnosis was based on clinical findings and serial biochemical tests and was confirmed in 18 by aspiration biopsy of the liver and in 27 others at autopsy. The majority of the patients (47) had hepatic cirrhosis, 13 had virus hepatitis, and 6 had miscellaneous disorders. The neuropsychiatric syndrome consists of progressive impairment of emotional control and intellect, the patient passing from stupor into coma. Common motor system signs are a "flapping tremor" of the outstretched hands and increased muscle tone, with hyperreflexia and ankle clonus. The treatment described is based on the concept that toxic nitrogenous substances of intestinal origin can be incriminated in the pathogenesis of hepatic coma. The intestines were emptied and kept free of all nitrogen-containing material. All dietary protein was stopped, and at least 1,600 calories were supplied daily as glucose drinks or as a 20% glucose solution through an intragastric drip. When necessary, a 40% dextrose solution was given intravenously via an antecubital vein into the innominate vein or superior vena cava, since small veins would be thrombosed by dextrose of this strength. Care was taken to avoid fluid overload. Chlortetracycline was given, and any precipitating factor was energetically treated.

Thirty-nine of the 66 patients recovered, 21 of the survivors having been in acute deep coma. Sodium glutamate was given intravenously on 12 occasions without clinical improvement. Thirteen patients with chronic neuropsychiatric changes (chronic portal-systemic encephalopathy) were maintained on low-protein diets for from 2 to 24 months without showing signs of protein malnutrition, and the serum albumin levels were well maintained. The prognosis was better in cirrhosis than in acute virus hepatitis and also if treatment was initiated in the precomatose stage. Outlook was also better when a clear precipitating factor, such as gastrointestinal hemorrhage, was amenable to therapy. In cirrhotic patients, when coma was associated with signs of liver failure such as ascites, jaundice, or a low serum-albumin value the prognosis was bad. When patients with acute hepatitis survived, they usually recovered completely. Seven of eight patients with cirrhosis who survived deep coma were alive a year later.

Thymectomy During Respiratory Failure in a Case of Myopathy with Myasthenia Gravis. S. G. Griffin, F. J. Nattrass and E. A. Pask. Lancet 2:704-707 (Oct. 6) 1956 [London, England].

The patient described presented an unusual myopathic picture, which, at the age of 35, was complicated by severe myasthenia, including virtually complete respiratory failure. Artificial respiration was maintained for several weeks, but it proved impossible to secure the return of breathing by the use of the usual antimyasthenic drugs. Eventually thymectomy was done while the patient was still in respiratory failure, and after the operation full respiratory power returned. The patient recovered to a condition as good as, or slightly better than, that which prevailed before the crisis, and he no longer requires neostigmine.

SURGERY

Complications of Thyroid Surgery. O. H. Beahrs, R. F. Ryan and R. A. White. J. Clin. Endocrinol. 16:1456-1469 (Nov.) 1956 [Springfield, Ill.].

Between 1940 and 1955, 14,374 thyroidectomies were performed at the Mayo Clinic. Thirty-seven (0.7%) of 5,402 patients undergoing thyroidectomy between 1940 and 1945 died at the hospital as compared with 9 (0.1%) of 8,972 patients who were operated on between 1946 and 1955. The obvious reduction of the death rate was the result of more careful selection of patients and the availability of antibiotic agents. The complications of thyroid surgery were reviewed for the year 1954, in the course of which 1,021 thyroidectomies were performed. The incidence of unintentional paralysis of the vocal cords was 1.3%. Tetany, which was not anticipated, occurred in only 0.2% of patients undergoing primary thyroid operation for benign goiter. Myxedema occurred postoperatively in at least 30% of the patients with thyroiditis. The only other significant complications consisted of hemorrhage in two patients, toxic psychosis in one, obstruction of the airway in two, and cardiac arrest in one. Fifteen tracheotomies were established prophylactically or as emergency procedures to alleviate airway problems.

Pericardiectomy for Chronic Idiopathic Pericarditis with Massive Effusion and Cardiac Tamponade. H. B. Shumacker Jr. and J. Harris. Surg. Gynec. & Obst. 103:535-538 (Nov.) 1956 [Chicago].

Chronic idiopathic pericarditis with massive effusion and cardiac tamponade may exist for long periods of time and may eventuate in chronic constrictive pericarditis. Its early management by extensive pericardiectomy is a relatively new concept. The authors cite the cases of two patients with massive effusion and cardiac tamponade who were effectively treated by extensive pericardiectomy. Patients with chronic idiopathic pericarditis with massive effusion and cardiac tamponade should be treated surgically at an early date. Though three reported patients treated by pericardiopleural fenestration did well, the authors feel that extensive pericardiectomy is the preferable procedure. The operation is technically easy, and the entire anterior and lateral surfaces of the pericardium can be excised. Such treatment removes the major portion of the primary disease. It brings to an early end the disabling consequences of cardiac constriction. It prevents the long-continued tamponade with its potentials for permanent myocardial damage. It eliminates the necessity of performing pericardiectomy later during the phase of constrictive pericarditis, when the operation is technically more difficult and somewhat more hazardous

Leiomyoma of the Jejunum with Hemorrhage. R. L. Bradley, E. H. Short and M. M. Klein. Radiology 67:576-577 (Oct.) 1956 [Syracuse, N. Y.].

The authors cite the case of a 74-year-old man in whom a smooth muscle tumor of the proximal jejunum, with a 6-cm. segment of intestine and its mesentery was resected. Smooth muscle tumors of the gastrointestinal tract are uncommon, and, in the absence of metastases, distinction between benign and malignant forms cannot be made grossly. Histologically, the presence of two or more mitotic figures per high-power field and poor differentiation indicate malignancy. The malignant tumors usually grow slowly and metastasize late. Surgical excision is the treatment of choice and affords a high percentage of cures. These tumors may be subserosal, intramural, or submucosal. The submucosal lesions may ulcerate and bleed or may lead to intussusception. When occurring in the duodenum, they mimic duodenal ulcer, with pain, spasm, and bleeding.

Circulatory Arrest After Profuse Hemorrhage with Special Regard to After-Treatment. I. H. Rygg and P. N. Pedersen. Nord med. 56:1275-1277 (Sept. 6) 1956 (In Danish) [Stockholm, Sweden].

Long-continued complete circulatory arrest occurred in a man aged 55 after profuse hemorrhage due to the severing of the ligature on the pulmonary artery shortly after the completion of left pneumonectomy. The chest was reentered and the pulmonary artery clamped, and the patient was resuscitated by cardiac massage and by rapidly instituted blood transfusion. He remained comatose for two days, after which improvement set in. There was grave psychic impairment without focal symptoms apart from left-sided paresis of the recurrent nerve as a result of the operation. Ambulant control four and a half months after the operation showed definite psychic improvement, Goldstein and Rohrschach tests indicated only slight psychic impairment of a focal type. The value in such cases of postoperative treatment consisting of oxygen therapy, induced hypothermia, and high intake of vitamins B, C, and E is stressed. If the patient can be brought through the acute stage, slow regression of the symptoms during the first year or years is seen. Decerebration, rigidity, and coma lasting over four days are unfavorable prognostic signs. In the case in question the prognosis ought to be relatively good with reference to the hypoxic injuries, as there has been steady improvement in vision, psychic condition, and the electrocardiogram.

Prevention and Control of Postoperative Wound Infections Owing to Staphylococcus Aureus. C. W. Howe. New England J Med. 255:787-794 (Oct. 25) 1956 [Boston].

The problem of wound infection caused by Micrococcus (Staphylococcus) pyogenes var. aureus has always been a prominent component of the over-all picture of surgical sepsis The extensive use of antibiotics in a hospital, by virtue of the emergence and dissemination of resistant strains, may intensify this problem to such an extent that the over-all infection rate is increased. This appears to have been the case in the Massachusetts Memorial Hospitals between 1949 and 1953. During the latter part of 1953 and early 1954 various measures to prevent cross contamination and the dissemination of antibiotic-resistant bacteria were inaugurated. Routine antibiotic prophlaxis on the house service was abandoned late in 1953 and by the middle of 1954 had been largely curtailed on the private service. The use of antibiotics was reduced to a minimum, being limited to treatment of established infections. It was recommended that bacteriological cultures be taken before giving an antibiotic, especially for patients with chronic or mixed infections or both. Micrococcic infections were treated with an appropriate combination of antibiotics. Since the nasopharynx is the natural reservoir for the Micrococcus, it was urged that two face masks, one over the other, be worn during operations and that they be changed by the circulating nurse every hour and a half during long procedures. A full 10-minute surgical scrub with a G-11 soap, at least for the first case, was advocated. Established principles of meticulous abdominal preparations, gentle atraumatic techniques, dry wounds, and careful closure were emphasized. Preventive measures on the wards consisted of the use of face masks for doctors, nurses, and patients and the use of gloves during the changing of septic dressings to help prevent the personnel from becoming carriers. Special septic sets were used containing the necessary instruments in an aluminum pan covered by a large, sterile, double-ply cloth wrapper. The set was unwrapped at the bedside, and at the conclusion of the dressing instruments, gloves, and other contaminated materials were deposited in the pan, which was then rewrapped and sent for autoclaving before cleaning and definite sterilization. Strict aseptic technique was applied to the dressing truck. Local isolation of infected wounds by impermeable occlusive dressings and of the nasopharynx and skin by masks and gloves proved feasible. Conversion of an infected wound into a clean one by immediate drainage and débridement under proper antibiotic protection was performed when possible, allowing early secondary closure.

Comparison of postoperative wound infection rates in surgical floor and operating-room patients in 1953, 1954, and 1955, and comparison of hospital carrier rates for M. pyogenes in the house surgical floor and operating room patients and personnel in August, 1953, and in August. 1955, showed that during the last two years the hospital carrier rate of Micrococcus and the incidence of penicillin-resistant strains in carriers have been significantly lowered, and the rate of postoperative wound infections has been reduced by almost half since the institution of the relatively simple program for the prevention of crosscontamination and judicious use of antibiotics. The prophylactic administration of antibiotics in civilian surgery is reasonable and helpful under certain circumstances, but the indications are limited and need further clarification. When adopted as a routine measure before and after all "clean" operations, it may be more harmful than beneficial. Emphasis is placed on well-established surgical and antiseptic techniques rather than prophylactic antimicrobial therapy.

Gastric Carcinoma in Identical Twin Women. G. A. Spikes, W. H. Yates, H. G. Liberty and H. Renger. A. M. A. Arch. Surg. 73:733-736 (Nov.) 1956 [Chicago].

The authors describe two fatal cases of cancer of the stomach in monozygotic twin women aged 66 and 67 in whom the tumor was apparently present simultaneously, although the symptoms began and the deaths occurred nearly a year apart. The cancers were not identical histologically, but both were adenocarcinomas arising in the gastric mucosa. The patients were considered monozygotic on the basis of their statements that they were often confused even by members of their own family and that their thinking and personalities were nearly identical. Their blood types were the same. Their heights and weights were almost identical. Coloring of the hair and eyes and general configuration of the face, ears, hands, and feet were the same. An exploratory laparotomy was performed in both patients and revealed an extensive neoplasm of the stomach that was not resectable. The diagnosis was established by biopsy of a large lymph node from the greater curvature of one patient and by biopsies of nodes from the greater omentum, the liver, and a wedge from the anterior stomach wall of the other patient. It seems doubtful that earlier diagnosis or suspicion of carcinoma in the second twin could have altered the outcome.

It has been stressed by some that tumors in identical twins occur at more nearly the same time, more often in the same place, and with more certainty than in nonidentical twins. It is by reason of this simultaneous occurrence that this knowledge will be of little help in treatment of carcinoma of the stomach, since by the time it is diagnosable it is often incurable. Only one other pair of identical twins dying of carcinoma of the stomach has been reported in the American literature; two pairs of twins with cancer of the stomach have been reported in the European literature. In the United States gastric carcinoma may reasonably be estimated to cause 50,000 deaths per year. About one person in 150 is an identical twin. Consequently, if there are no determinants save chance, over 300 identical twins should die in the United States annually from gastric carcinoma. Carcinoma of the stomach occurred in only one twin of each of the two pairs of identical twins whose cases were collected from the European literature; the other twins were unaffected for 16 and 7 years respectively. The presented evidence tempers the older concept that monozygous twins must necessarily have simultaneous identical tumors. While a general predisposition might lead to tumors in each of a pair of twins, it could not explain their identical location or simultaneous occurrence.

Giant-Cell Tumors of Bones. C. Zuckermann. Rev. mex. cir. ginec. y can. 24:195-216 (July) 1956 (In Spanish) [Mexico, D. F., Mexico].

Multinuclear giant-cell tumors of the bones are, as a rule, benign, but they may be cancerous and produce metastases. Tumors of this kind develop selectively on the epiphyses, mainly those of the femur, tibia, radius, and humerus. They also develop on the maxilla and the bones of the cranium, the hands, and the feet. They constitute 20% of all tumors of the bones. They are huge, rapidly recurring, do not respond to treatment, and cause fractures and local destruction of bone. The early symptoms consist of subacute local pain and moderate changes in the bone, which can be visualized by roentgen examination, disclosing the roentgen picture of osteolysis. The diagnosis is made by clinical and roentgen examination and biopsy. The tumors can be differentiated from bone cysts, parathyroid osteosis, osteosarcoma, osseous metastases of cancer, and osseous eosinophilic granuloma. The treatment consists of roentgen therapy or surgery (resection of the tumor segment of the bone or amputation). Ten patients were observed. The tumor was cancerous in two and benign in eight. Treatment of cancerous tumors consisted of disarticulation of the hip joint in one patient and of amputation of the thigh in another. In the eight cases of benign tumor the treatment consisted of amputation in two, segmental resection in three, and roentgen therapy in three. Amputation was resorted to in a patient with a huge femoral tumor and in another with a recurrent tumor of the tibia.

Dermatome Débridement and Early Grafting of Extensive Third Degree Burns in Children. I. A. Meeker Jr. and W. H. Snyder Jr. Surg. Gynec. & Obst. 103:527-534 (Nov.) 1956 [Chicago].

During the 18-month period from September, 1954, to April, 1956, 13 children with third-degree burns covering from 15 to 65% of the total body surface were admitted to the Los Angeles Children's Hospital. The areas of full-thickness burn injury were débrided in stages with an electric dermatome. This new technique of dermatome débridement in extensive third-degree burns permitted early grafting and more rapid wound closure and resulted in a more than 60% reduction in the length of hospitalization. It was achieved without incurring massive blood loss or inadvertently destroying viable skin, as has occurred with other forms of surgical débridement. To protect against serious wound infection, bacteriostatic dressings employing tetracycline hydrochloride were applied continuously during all phases of treatment until complete epithelization of the wound had taken place.

It is practical to manage major third-degree burn injuries from the onset by a series of planned, staged surgical procedures involving dermatome débridement and subsequent early grafting. Dermatome débridement has proved to be a safe, satisfactory technique for removing extensive burn eschar. When such débridement is followed by early extensive grafting, the patient's pain and suffering is immeasurably reduced, the care of the patient is simplified for the surgical and hospital staffs, and the period of hospitalization is shortened. It is estimated that 840 days (or 2.3 years) of hospitalization were saved in 12 children with severe burns who were treated with dermatome débridement instead of by standard methods.

A Twenty Year Follow-Up in Fifty Below Knee Amputations for Gangrene. B. C. Smith. Surg. Gynec. & Obst. 103:625-630 (Nov.) 1956 [Chicago].

Smith has used a modified guillotine amputation below the knee for gangrene of the extremity in patients with diabetes and arteriosclerosis since 1930, primarily because of the advantages of preserving the function of the knee-joint and because of the poor results obtained with amputations through the thigh. He describes his technique of the below-the-knee amputation and reviews the results in 50 patients. Six of them died in the hospital; 5 lived less than a year; 17 died between 1 and 5 years after operation; 9 survived from 5 to 10 years and 6 for 10 to 15 years; 5 lived over 15 years; and the remaining 2 could not be traced. The average survival was five and one-half years, and 81.2% of the stumps were suitable for prostheses. The large number rehabilitated to full-time or part-time work, the mortality of 12% (which should be improved with more careful selection of cases), the reamputation rate of 6%, and the fact that 42% of bilateral amputees are using artificial legs constitute factors sufficiently encouraging to warrant the abolition from textbooks and from teaching institutions of the doctrine that thigh amputation is the method of choice in such patients.

Periodic Benign Synovitis: Idiopathic Intermittent Hydrarthrosis. A. D. Weiner and R. K. Ghormley. J. Bone & Joint Surg. 38-A:1039-1055 (Oct.) 1956 [Boston].

Periodic benign synovitis is characterized by the regular cyclic recurrence of articular pain, swelling, or limitation of motion without permanent deformity of the joint or injury to the bone. The common features, general pattern, and response to therapy of this disease for which various other terms, and among them idiopathic intermittent hydrarthrosis, had been suggested were studied in 14 male and 33 female patients between the ages of 13 and 45 years. They were selected from 1,800 patients seen at the Mayo Clinic between 1930 and 1954 by using the following diagnostic criteria: recurrence of articular symptoms at regular intervals; complete freedom from signs and symptoms between attacks; absence of systemic reaction; and absence of a specific causative factor that would account for the articular symptoms, i. e., bacteria, rheumatic fever, trauma, and purpura. Although one or both knees were involved in 40 of the 47 patients, any peripheral joint may be involved with the disease.

Specimens of synovial membrane were obtained from the knees of 10 patients by needle biopsy or surgical incision. Microscopic examination of these specimens revealed a picture similar to that seen in cases of rheumatoid synovitis. The villi were edematous to a greater or lesser degree and were hyperemic. The vessels in the villi appeared somewhat dilated and occasionally had thickened walls. Occasionally the synovial membrane and villi were markedly infiltrated with plasma cells and lymphocytes. The cellular infiltration was sometimes focal and confined to perivascular regions and other times was diffuse. Workers who consider this microscopic picture as pathognomonic of rheumatoid arthritis may conclude that periodic benign synovitis is a rare form of rheumatoid synovitis; those who consider this histological reaction as a nonspecific one may favor the concept that periodic benign synovitis is a separate and distinct entity.

Spontaneous remissions were frequent, and results of medical and surgical treatment were particularly difficult to evaluate. Thus far no medical therapy, including administration of acetylsalicylic acid (aspirin), corticoid preparations, diethylstilbestrol, vitamin D, sodium cacodylate, gold, and antihistaminics, has proved to be consistently effective. Synovectomy appeared to be efficacious in some patients with severely affected knee joints, but even this form of treatment was not completely successful.

Chondrosarcoma, a Surgical and Pathological Problem: Review of 212 Cases. D. C. Dahlin and E. D. Henderson. J. Bone & Joint Surg. 38-A:1025-1038 (Oct.) 1956 [Boston].

One hundred thirty-eight male and 74 female patients between the ages of 9 and 79 years with chondrosarcoma of the trunk and extremities were operated on at the Mayo Clinic between 1905 and 1955. The tumors were found in the trunk and the upper ends of the femurs and humeri in 178 (84%) of the 212 patients, and only four tumors were found in the hands and feet. Five patients died in the postoperative period. Of the remaining 207 patients, 122 were considered to have had inadequate surgical treatment and 85 were considered to have had adequate surgical treatment. There were recurrences after the original surgical procedures in 154 patients. In 139 of these, the longest interval between two consecutive appearances of the tumor was less than 5 years; in 14 the longest such interval varied between 5 and 10 years; and in only 1 was the interval more than 10 years. Consequently a 10-year interval without further appearance of the tumor is necessary to establish a cure. It is important that this interval be counted from the last surgical attack on the tumor and not from the first appearance of symptoms. Nine of the 122 patients in the inadequately treated group could not be traced, and 4 others had the last surgical treatment within the last 10 years. Four (3.7%) of the remaining 109 patients have gone more than 10 years without recurrence and are considered to be cured; 80 are dead as a result of the disease; and an additional 25 have had massive recurrence and are also considered therapeutic failures. Fourteen of the 85 patients in the adequately treated group could not be traced, and an additional 37 had received their surgical treatment within the last 10 years. Fourteen of the remaining 34 patients who are eligible for determination of a 10-year survival are alive and well; thus adequate therapy was successful in 41% of the patients traced.

Nuclear pleomorphism, hyperchromatism, and increased number of multinucleated cells were the important features indicative of greater cytological activity, and these features were used in grading the tumors on the basis of their cytological appearance. Four patients had "borderline" tumors according to Lichtenstein and Jaffe's histological criteria, 116 patients had grade 1 tumors, 79 had grade 2 tumors, and 13 had grade 3 tumors. The grades showed some correlation with prognosis. Increased cellular activity sufficient to change the numerical grade was observed in 13 of the recurrent tumors. In eight of these, the periphery of the lobules of the recurred lesions showed a spindling of the tumor cells that occasionally resulted in areas of frank fibrosarcoma. Zones of osteogenic sarcoma were observed in two recurrent tumors. The histological changes in these 13 cases were accompanied by a clinical course that included the development of distant metastasis in several instances. The grade of the malignant growth was higher than grade 1 in only 2 of the 18 patients in whom the results of surgical treatment were considered successful after long-term follow-up. The grade of the malignant growth was higher than grade 1 in 56 of the 125 patients in whom the results of treatment were unsuccessful. Metastasis occurred in 33 patients; 14 of the metastasizing tumors were grade 1, 14 were grade 2, and 5 were grade 3. Implantation of the chondrosarcomas was the usual cause of recurrence in the patients treated inadequately. In other patients implantation occurred in biopsy or other incisions. Fifty-eight patients received roentgen irradiation, and 15 of these seemed to derive definite benefit in that the tumors regressed in size and the symptoms were somewhat relieved, although the ultimate course of the disease was not altered.

Chondrosarcoma is a neoplasm of slow growth that usually causes the death of the patient by local enlargement but that may metastasize through the blood stream or the lymphatic system. It is important to differentiate it from the nonmalignant chondromatous variants. Microscopic examination of biopsy material permits prediction of malignant course. Local control of the tumor by adequate treatment is the chief problem in therapy. Recurrence of the tumor in the proximal part of the extremity or in the trunk represents an irrevocable failure of treatment in most patients. The ease with which chondrosarcoma implants locally in surgical wounds, including biopsy wounds, constitutes a major problem in management. Osteogenic sarcoma with a prominent chondroid component should not be grouped with chondrosarcoma.

Fatigue Fissure (March Fracture) of the Tibia. H. van der Houwen Nederl. tijdschr. geneesk. 100:2521-2524 (Sept. 1) 1956 (In Dutch) [Haarlem, Netherlands].

The author observed six patients with occult fractures of the tibia in the course of 18 months in a military hospital. Three young men had fatigue fractures of both tibias. One complained of pain in the left tibia about a handbreadth above the ankle. He felt some pain on pressure, but the pain was most severe when he walked. He did not recall any injury, but he had done much walking. Roentgenoscopy revealed no changes at this time, but six weeks later a painful thickening of the tibia could be felt and roentgenography now showed a periosteal reaction. Treatment consisted of limitation of standing and walking. Several months later pain developed also in the right tibia, and a periosteal reaction was visible a little higher up than on the left side. The histories of the two other patients were similar.

Repeated roentgenographic examinations may be necessary to demonstrate these fractures, for, whereas no change may be visible shortly after the appearance of the pain, some weeks later the periosteal reaction is quite evident. The author points out that, whereas fatigue fractures of the foot (march-foot) are a well-known defect in military personnel, it is not so well known that fatigue fractures may also develop in other bones.

Intramedullary Fixation of Long Bone Fractures. L. W. Breck. Am. Surgeon 22:1005-1013 (Oct.) 1956 [Baltimore].

Breck reviews the history of intramedullary fixation of bone fractures and describes his experiences with the method, particularly in fractures of the femur and tibia. He has employed the Hansen-Street nail for intramedullary fixation of fractures of the femur since 1949 and has obtained excellent results. Union occurs in from 95 to 100% of the cases. Early ambulation is permitted, and a cast is not used. The Lottes' nail is employed by the author exclusively for intramedullary fixation of the shaft of the tibia, because the V-nail of Küntscher was not exactly the right shape, nor was it quite strong enough. The Lottes' nail is triangular in shape and the cross section of the tibia is also roughly triangular. Union was obtained in all of the 26 patients with fractures of the tibia in which the author employed the intramedullary nail.

Intramedullary fixation is the best method of treatment also in fractures of the clavicle that require open reduction, although open reduction is not needed very often in fractures of this bone. However, when the fracture cannot be reduced at least fairly satisfactorily, or where there is going to be a marked prominence at the fracture site because of an upward projection of the distal end of the proximal fragments, open reduction usually is indicated. In the author's experience about 25% of adults with clavicular fracture require open reduction. In fractures of the forearm, intramedullary fixation has not proved definitely superior to other methods, but partially threaded round pins, Street's new square pins, or certain other intramedullary devices may be used. In the treatment of fractures of the shafts of the metacarpals and metatarsals, intramedullary fixation may sometimes be useful, but, on the whole, other methods of treatment are as good or better in these locations. Intramedullary fixation of fractures of the shaft of the humerus is not generally a satisfactory method.

Streptokinase and Streptodornase and the Prevention of Postsurgical Peritoneal Adhesions. A. Innocenzi and I. Priola. Minerva chir. 11:823-827 (Sept. 15) 1956 [Turin, Italy].

The authors studied the effect of streptokinase and streptodornase on postoperative adhesions. Experiments were conducted on 24 adult male rabbits weighing from 2 to 3.5 kg. each. Animals were divided into three groups of eight each, the first group being kept as a control. Streptococci were introduced into the peritoneum of the animals of the second group during surgical intervention. Streptococci were introduced in small doses into the peritoneum of the animals of the third group every day for 10 days. All animals were operated on under thiobarbital anesthesia. The doses used in the animals of the second group were 500,000 units of streptokinase and 125,000 units of streptodornase; for the animals of the third group the total dose was 1 million units of streptokinase and 250,000 units of streptodornase. Exploratory laparotomy was performed 15 days after the intervention. Only one animal died. Large adhesions were found, especially between the stomach and the abdominal wall, in seven animals of the first group. Thin and transparent adhesions were found in four animals of the second group. No adhesions were found in the animals of the third group. There were no cases of toxicity or irritation. The best results were obtained in animals operated on with sterilized material.

Heparin in Thrombosis and Embolism: Fifteen Years' Experience. I. O. Brennhovd. Nord. med. 56:1325-1328 (Sept. 13) 1956 (In Norwegian) [Stockholm, Sweden].

Heparin was given to 197 patients with thrombosis or embolism representing mainly postoperative complications. The drug was given intravenously in daily doses of from 250 to 450 mg. in four injections, without control of the coagulation time. The treatment was continued until the patient was up, and in some cases also as a long-term treatment with reduced dosage and one or two injections daily. A certain variation in the amount needed depends on the individual response. Heparin treatment of thrombosis and embolism was found to shorten the duration of the disorder and to result in a low mortality from the complication in the acute stage. Late complications after thrombosis or embolism treated with heparin are few and presumably depend on the localization and extent of the thrombosis when diagnosis is made. Follow-up of 165 patients showed that half the patients had no sequels of the thrombosis, 38% had an insignificant swelling of the calf, and 12% had severe sequels. Hemorrhagic complications in heparin treatment are believed to be readily met with protamine sulfate. Because of the awkward form of administration, heparin is not an ideal agent for long-term treatment. It seems to be the ideal treatment in the acute phase of thromboembolism and the only treatment in cases where the patient can be mobilized in bed early and is not subjected to long confinement to bed. According to Jorpes, six days' ineffective treatment with heparin points to possible complications other than thrombosis or embolism.

NEUROLOGY & PSYCHIATRY

Meninges and Choroid Plexuses in Acute Anterior Poliomyelitis. G. C. Angela and G. Giuliani. Minerva med. 47:657-661 (Sept. 15) 1956 (*In Italian*) [Turin, Italy].

The authors studied the meninges and the choroid plexuses obtained from the autopsy of 15 patients who died of acute anterior poliomyelitis. Meningeal alterations along the neuraxes and the locations of these alterations in relation to the nervous tissue underneath were searched for. The choroid plexuses of the fourth and lateral ventricles were systematically examined. A marked hyperemia of the meningeal vessels could be seen macroscopically. Macroscopic examination did not show any marked alterations in the choroid plexuses; there was, however, some evidence of passive hyperemia and of some edema. Microscopic examination showed marked changes in the structure of the meninges. The nervous tissue underneath was often altered, but at times it was intact. There were no important changes in the ependyma of the brain, of the ventricles, and of the central canal of the spinal cord. The authors think that in cases of nonparalytic acute anterior poliomyelitis there is a meningeal reaction that is similar histologically to a serous reaction.

Paralysis of the Bladder in Poliomyelitis. F. Di Nola and G. C. Angela. Minerva med. 47:655-657 (Sept. 15) 1956 (In Italian) [Turin, Italy].

The authors found paralysis of the bladder in 5.9% of the patients with poliomyelitis treated in their hospital from 1951 to 1953. Remission ensued in from 10 to 15 days. Results are given of a study made on more than 20 monkeys injected with poliomyelitis virus of the Brunhilde strain. Paralysis followed in from six to nine days. Paralysis of the bladder was found in 20% of the animals. The parasympathetic cells of the excretory sacral nuclei appeared intact. The complete recovery of the excretory function in all cases indicates that vesical paralysis must be the result of functional and not of anatomic lesions.

Intra-arterial Growth Hormone Treatment in Chronic Poliomyelitis: Results in 12 Cases. E. Henríquez Inclán. Medicina 36:359-374 (Aug. 10) 1956 (In Spanish) [Mexico, D. F., Mexico].

Satisfactory results from intra-arterial injections of growth hormone are reported in 12 patients between the ages of 2 and 15 years with chronic sequels of poliomyelitis. Sequels had lasted between 6 months and 15 years. Medical and surgical treatment failed. Four patients had the treatment only in one leg and eight patients had it in both legs. The growth hormone was given in doses that varied between 1 and 2 cc. in 1.5 cc. of saline solution for each injection. The injections were given once a week to a total of from three to eight injections for each leg treated. The patients were observed for one and a half to four months. It was observed that the necessary period for appearance of favorable results of the treatment of the leg depends on the chronicity and the degree of paralysis. When muscular movement of the legs is present, even if moderate before the treatment, the movements increase from the very first injections, and they continue to improve as the treatment progresses. The general reaction of the leg to the treatment is manifested by improvement (or appearance) of muscular movement, improvement of the muscular tonicity and of the local temperature of the skin, and appearance or increase of patellar, plantar, and achilles reflexes. The muscles increase in thickness and the leg in size during a period that varies between two and four weeks. The muscular reaction to faradic and galvanic currents and the chronaxia of the muscle increase. The results are marked for the leg in which the injections are given and moderate for the leg in which they are not. A histological study was made of a portion of a gemellus muscle before start of the treatment, and on the 20th day of its course there was a marked increase of the number of capillaries and improvement of the muscular tissue toward a normal aspect. The treatment is harmless. This is a preliminary report.

Effect of Unabsorbed Radiographic Contrast Media on the Central Nervous System. F. L. Davies. Lancet 2:747-748 (Oct. 13) 1956 [London, England].

A follow-up of 119 patients who had undergone 125 myelograms for various diseases of the spinal cord from 1 to 15 years earlier are reported. Myodil was used in 124 cases and Lipiodol in one. The length of follow-up was from 1 to 15 years. The average amount of medium injected was 5 ml.; not less than 3 ml. or more than 6 ml. was ever used. An attempt at removal of the medium had been made in only six cases, but all the patients showed residual contrast medium in the subarachnoid space: in one it was present within the cranial cavity only, in 68 in the spinal theca only, and in 50 in both situations. Seventy patients manifested abnormal reactions to the injection of the contrast medium, in 56 they were noted immediately after the injection or within a few hours, and in 14 the symptoms had persisted or had developed later and were found when the patients were examined a year or more after the myelography. The immediate reactions were severe in 47 and mild in 9. Headache, alone or with neck stiffness, nausea, vomiting, and giddiness, was common. Severe pain in the spine, usually lumbar but occasionally cervical, was also common. The symptoms lasted from a few hours to 14 days. Meningism, cranial-nerve palsy, and nystagmus followed cisternal myelography. The symptoms of meningism lasted three days, the cranial nerve palsy three weeks, and the nystagmus two weeks.

While the true incidence of persistent symptoms due to unabsorbed contrast medium is difficult to assess, they were significant in 14 patients in this series. Laminectomy was performed on five patients a year or more after myelography. In four patients it was the second operation, and in each case the arachnoid was found to be thickened and lined by a tough sticky white exudate. The nerve roots were adherent to the exudate. Three patients who had undergone myelography from one to four years previously died from causes other than their original disease. In all three the pia-arachnoid showed changes similar to those found in the surgical cases. The proportion of severe symptoms cannot be ignored and shows that there is need for restraint in employing this procedure. The contrast medium should be removed, if possible, after myelograhpy.

The Emotional Factor and the Epileptic Attack. I. M. Allen. New Zealand M. J. 55:297-308 (Aug.) 1956 [Wellington, New Zealand].

The clinical material on which this study is based consists of (1) the 182 patients with epileptic symptoms most recently examined in detail; (2) the first 622 patients with epileptic symptoms examined from 23 years ago, for purposes of comparison and control of the interpretation of the clinical data; and (3) the case material on which studies were made on reflex epilepsy, myoclonus epilepsy, epileptic automatism, temporal lobe discharges, small epileptic attacks, forced thinking as part of the epileptic attack, and other aspects of epilepsy. It was found that the emotional factor has an effect in aggravating the frequency and severity of epileptic attacks in over one-quarter of the cases. Facts show that the association of the emotional factor and the epileptic discharge is in most cases of general rather than local significance so far as the original site of discharge is concerned, that an association based upon the production of biochemical changes, effects on the blood pressure, or conditioning at the level of the cerebral cortex is uncommon; that an association based on the origin of the discharge in the temporal lobe is also very uncommon and even rare; that the association can usually be recognized by study of all aspects of the history and variations found on examination; and that treatment directed to it may in favorable cases eliminate one of the most potent factors precipitating epileptic symptoms in the individual who is prone to them

PEDIATRICS

Treatment of Chorea Minor with Prednisone and with Prednisone Associated with Chlorpromazine. I. Lanza and R. Morbidelli Minerva pediat. 8:1131-1134 (Sept. 22) 1956 (In Italian) [Turin, Italy].

The authors treated 10 patients with chorea minor with prednisone and with prednisone combined with chlorpromazine. Patients were divided into two groups of five patients each Rheumatic etiology was presumed in the patients of the first group. Prednisone alone or combined with penicillin or methylandrostenediol was given. Remission of the symptoms followed in a relatively short time. Starting dose was 1.5 to 2 mg. per day for each kilogram of body weight, continued for from two to three days. Maintenance dose was from 0.5 to 1.5 mg. per day for each kilogram of body weight, continued for at least 15 days.

Patients of the second group received prednisone combined with chlorpromazine. Two milligrams of the combination per each kilogram of body weight per day were given. Three patients in whom the origin of the disease was rheumatic improved markedly. Two patients in whom the etiology of the disease was unknown took a longer time for recovery: in one remission of the symptoms followed after 12 days, and the other improved very slowly within a month. No untoward side-effects were noticed.

The Changing Pattern of Rheumatic Heart Disease: The Experience in New York City Department of Health Cardiac Consultation Clinics, 1943 to 1953. L. Kuskin and M. Siegel. J. Pediat. 49:574-582 (Nov.) 1956 [St. Louis].

An analysis was made of the clinical diagnosis carried out in 65,044 children who were examined at the Cardiac Consultation Service Clinics of the New York City Health Department between 1943 and 1953, in order to determine whether there has been a change in the relative frequency of organic heart disease after rheumatic fever. The relative frequency of detectable heart disease occurring in children with a history of rheumatic fever who were referred to the consultation service from child health stations, elementary and high schools, mercantile working paper clinics, private physicians, and, on occasion, hospital clinics and community welfare agencies, decreased from about 60% in 1943 to about 30% in 1948. The 30% frequency level has been maintained since 1948.

These findings are related in time to the widespread use of antibiotics and are consistent with the decrease in prevalence of rheumatic heart disease reported from other source material by various investigators. They represent supportive data on the changing pattern of rheumatic heart disease.

Salicylate Intoxication. H. D. Riley, Jr. and L. Worley. Pediatrics 18:578-594 (Oct.) 1956 [Springfield, Ill.].

Salicylate intoxication occurred in 42 children between the ages of less than 1 and 6 years at the Vanderbilt University Hospital in Nashville, Tenn., between 1945 and 1955. Poisoning was caused by acetylsalicylic acid (aspirin) in 41 patients and by sodium salicylate in one. It occurred as a complication of therapy for some concomitant disease in 29, 6 of whom had rheumatic fever, and was the result of accidental ingestion in 13. Most of the accidental cases occurred in children between the ages of 2 and 4 years, the age of insatiable curiosity and some measure of independence. Therapeutic intoxication occurred chiefly in infants less than one year of age. Cumulative therapy intoxication is more likely to occur in infants than in older children not only because of an unawareness of the dangers and of the proper dose of acetylsalicylic acid but also because of the decreased renal excretion of salicylates due to renal immaturity and prerenal azotemia caused by dehydration resulting from the disease for which the drug is given.

The response of the individual patient to the salicylate varied considerably. Even in poisoning resulting from accidental ingestion, in which the effects of an underlying disease do not have to be considered, the plasma concentration of salicylate, clinical response, degree of toxicity at a given concentration of salicylate, and time required for renal excretion varied greatly for children of the same age and size who ingested comparable amounts of salicylate. Severe intoxication at low concentrations of salicylate in the plasma was observed. Hyperventilation and vomiting were the most common clinical manifestations of salicylism, but a hemorrhagic diathesis caused by hypoprothrombinemia; hyperpyrexia; delirium or coma; circulatory collapse; and respiratory failure were occasionally observed.

Because of the unique effect of salicylates on acid-base balance, with an initial respiratory alkalosis progressing to a metabolic acidosis, treatment must be individualized, flexible, and directed by physiological principles. The increased metabolic rate, polyuria, diaphoresis, and the need for enhanced urinary volume demand that adequate amounts of fluids be provided. Until serum pH and carbon dioxide concentrations have been determined, dextrose solutions to equal full maintenance and estimated deficit requirements should be administered intravenously. If respiratory alkalosis exists, sodium chloride solution should be added to the parenterally given fluids so that salt depletion can be avoided. Convulsions should be treated by administration of oxygen; tetany can be controlled by administration of calcium gluconate or inhalations of 5% carbon dioxide. If and when acidemia occurs, alkalinizing salts should be administererd. Shock should be combatted with whole blood, albumin, and plasma transfusions. Barbiturates should not be routinely used in an effort to decrease the hyperventilation, but might be used as a last resort in certain cases. A clinical trial with exchange transfusions is warranted in selected cases of salicylate poisoning.

Five patients died, and it seemed that the combination of the disease, for which the acetylsalicylic acid was given, with the salicylate poisoning was responsible for the deaths. The important role of acetylsalicylic acid ingestion as a cause of death is reemphasized and a plea is made for better education and attention to the potential dangers of salicylates.

Congenital Endocardial Fibro-Elastosis: II. A Clinical and Pathological Investigation of Those Cases Without Associated Cardiac Malformations Including Report of Two Familial Instances. J. Kelly and D. H. Andersen. Pediatrics 18:539-555 (Oct.) 1956 [Springfield, Ill.].

Seventeen cases of congenital endocardial fibroelastosis without associated malformations of the heart or great vessels and without myocarditis or other known cause for the cardiac changes were selected from the autopsy protocols of 237 children aged less than 13 years with congenital heart disease who died at the Babies Hospital in New York City in the course of a 20-year period ending June, 1955. Seventy-nine similar cases have been collected from the literature. Two instances of familial incidence were present in 3 of the 17 cases. There were several instances of the disease in one or more of multiple births, and three instances of two affected siblings among the 79 cases.

Evidence is presented that the 96 cases of congenital endocardial fibroelastosis without associated cardiac malformations represent a disease entity with the following characteristic features: 1. The disease is familial. 2. Nonspecific symptoms begin in the first six months of life in most patients; they consist of failure to gain weight and of cough, over a few days or weeks. A sudden attack of labored breathing and tachycardia with vomiting or abdominal pain may lead to death within one or two days or to recovery followed by repetition of similar attacks. Death within a day of onset of an attack occurs in 50% of the patients. 3. The heart is grossly enlarged, mainly because of dilatation and hypertrophy of the left ventricle. 4. The endocardial fibroelastosis increases with age and is most pronounced in the left ventricle. 5. Noncardiac malformations are rarely present. 6. Bradycardia before birth and congenital heart block occurred in 2 of the 17 patients.

The reported data are compatible with the hypothesis that the disease represents a congenital familial metabolic defect leading primarily to weakness of the myocardium and secondarily to fibrosis of the endocardium.

Atrial Flutter in a Newborn Infant. J. A. Segal. Connecticut M. J. 20:700-702 (Sept.) 1956 [New Haven, Conn.].

The author reports an instance of atrial flutter with 2:1 block in a newborn baby. The rapid regular heart rate was discovered three days before birth at a routine prenatal checkup. Examination of the baby shortly after birth revealed a heart rate of about 200 per minute and some slight cyanosis of the extremities. The next day there was evidence of early heart failure. An electrocardiogram taken 20 hours after birth revealed atrial flutter with 2:1 block. An x-ray on the same day showed cardiac enlargement. Digitalization converted the atrial flutter into normal sinus rhythm within 24 hours. An x-ray taken three days later showed some shrinking of the cardiac silhouette. The baby was discharged from the hospital in good condition on the 16th day.

Progeria: Report of a Case with Cephalometric Roentgenograms and Abnormally High Concentrations of Lipoproteins in the Serum. *I. M. Rosenthal, I. P. Bronstein, F. D. Dallenbach and others. Pediatrics* 18:565-577 (Oct.) 1956 [Springfield, Ill.].

The authors describe a typical case of progeria (Hutchinson-Gilford syndrome) in a girl, in whom the diagnosis was made at the age of 20 months. The patient was followed up to the time of her death, which occurred at the age of 11 years as the result of an accident at school. Analysis of cephalometric roentgenograms of the patient revealed that the characteristic facial expression of progeria resulted from pronounced retardation of facial growth in the presence of relatively normal growth of the neurocranium and was therefore not the result of premature aging. Atherosclerosis was revealed by autopsy. Concentrations of lipoproteins in the serum were determined by analytic ultracentrifugation during life and were found to be abnormally high, suggesting a metabolic error rather than premature aging of the arteries as the cause of the atherosclerosis. Psychological studies showed the patient to be of normal intelligence with no evidence of senilism. Analysis of these data leads to the conclusion that premature aging does not occur in progeria.

DERMATOLOGY

Cutaneous Leishmaniasis: A Report of 10 Cases. P. H. Langsjoen. Ann. Int. Med. 45:623-639 (Oct.) 1956 [Lancaster, Pa.].

The author reports observations on 10 American soldiers who had contracted cutaneous leishmaniasis in the area near Camp Pina in the Panama Canal Zone. This disease is generally believed to be transmitted by the bite of an infected sandfly. The area in which these soldiers were operating was heavily infested with the phlebotomus fly. There was evidence that all patients were infected while on jungle maneuvers, probably at night, while sleeping, and during the dry season. The clinical features of a classic case—the oval, painless, indolent ulcer with the raised dull red border, the necrotic base, and the beadlike subcutaneous nodules—are almost diagnostic. The ulcer expands by concentric zones of parasitic expansion just under the epidermis among the dermal papillae. The raised red border represents this expanding zone of active inflammation. It is the locus of active disease and the place from which the best material for diagnostic purposes can be obtained. Cold compresses were applied initially until the crusts and purulent material were cleaned up. Then the area was blocked with procaine, and the undersurfaces of the raised borders were scraped with a small curet. The material obtained was then smeared on a slide like an ordinary blood smear and stained with Wright's stain. The Leishmania organism is small, measuring from 2 to 5 μ in the longest diameter; it can be seen only under oil immersion. It is oval in shape and has well-defined cell borders, light blue cytoplasm, a large, relatively pale trophonucleus at one end of the cell, and a dark, rod-shaped blepharoblast. These organisms may be seen either singly, in groups, or within the structure of large macrophages. The visualization of the organism is diagnostic.

All patients were treated with intramuscular injections of the antimony preparation stibophen (fuadin), which produced cure in from 15 to 28 days, but four patients experienced recurrences and required a second course of stibophen therapy. Electrocardiographic changes indicative of antimonial intoxication were observed in all patients. Arthralgia developed in four patients during the first course of treatment and in all patients requiring a second course. All toxic changes were reversible. Stibophen (fuadin) is an effective and relatively safe form of treatment in otherwise healthy young white males with leishmaniasis, but the therapy is quite prolonged.

Localized Cutaneous Histoplasmosis. W. S. C. Symmers. Brit. M. J. 2:790-792 (Oct. 6) 1956 [London, England].

Solitary localized histoplasmic granulomas of the skin were found and confirmed by isolating Histoplasma capsulatum from the skin lesions of two patients, a 28-year-old Nigerian man and a 23-year-old Nigerian woman who were living in England at the time the diagnosis was made. The skin lesion was on one cheek in the man and over the lower end of the sternum in the woman. The organisms in the granulomas were of the large cell type, which had been described as H. duboisii; their cultural characteristics were typical of H. capsulatum. The infection was contracted in West Africa in each patient.

Lupus Erythematosus Treated with Mepacrine: Results of Treatment Together with Report of Cases with Recurrence on Longer Observation Period. J. P. Nielsen and J. V. Christiansen. Ugesk. læger 118:1035-1045 (Sept. 6) 1956 (In Danish) [Copenhagen, Denmark].

In 1953-1954, 97 cases of lupus erythematosus (81 of discoid type, 16 of erythematous type) were treated with mepacrine, the total dose being between 1.6 and 49.8 gm. and the average dose, 18 gm. In the first group there were excellent results in 22 patients, improvement in 34, and no or doubtful results in 25; in the second group excellent results were seen in 9 patients, improvement in 5, and no or doubtful results in 2. Fully half the patients were hospitalized during part of the treatment. No difference was demonstrable between the results in the hospitalized and the ambulant groups. Sex and duration of the disease seem to be unimportant, but extensive involvement appears to give a somewhat poorer result. Most surprising was the better prognosis for patients over 60. The etiology of lupus erythematosus is unknown. Side-effects in the form of dermatitis occurred in 5 patients, 16 had dyspepsia, and in 8 there were disturbances in sweating. Observation for about a year after the termination of treatment showed aggravation in about 80% of the patients who originally responded to the treatment. No recurrence was found after the 12th month, but only five patients were observed for over a year. The large number of recurrences within a year indicate that the treatment is symptomatic and not curative. Excellent results have been reported after chloroquine treatment of lupus erythematosus. The substance does not cause yellow coloration of the skin and causes fewer side-effects than mepacrine. Interest centers about the extent to which chloroquine in low doses can reduce the tendency to recurrence.

OTOLARYNGOLOGY

Otitic Meningitis: A Review of Cases in an Attempt to Evaluate the Results of Treatment. J. B. McBean. A. M. A. Arch. Otolaryng. 64:253-257 (Oct.) 1956 [Chicago].

Data on a group of 15 patients who had meningitis associated with acute or chronic otitis media are presented. The patients were observed at the Mayo Clinic during the 10 years from 1946 through 1955. Five of the six deaths occurred in patients with acute otitis media, and the sixth occurred in a patient in whom it was not determined whether the otitis was acute or chronic. Five of the six deaths occurred in patients in whom Diplococcus pneumoniae was identified in the spinal fluid; in the sixth, no organism was identified. All the patients who had meningitis with chronic otitis media received appropriate otologic surgical treatment and adequate antibiotic and chemotherapy, and all recovered. It seems probable that, in the patients who died, the diagnosis of otitis media or meningitis was not made early enough or that adequate antibiotic therapy or chemotherapy had not been given prior to hospital admission. Patients with acute otitis media and meningitis who recovered all received relatively large doses of antibiotic agents and sulfonamide. Although meningitis is a relatively rare complication of otitis media, the 40% mortality (six deaths in 15 patients) indicates that it is extremely serious. Fulminating meningitis might be prevented by early diagnosis and vigorous treatment of acute otitis media. To facilitate early diagnosis of meningitis the author recommends that spinal puncture be performed in patients with unexplained fever, convulsions, and headache; this would result in earlier institution of adequate therapy.

Improvement of Hearing in Otosclerosis by Means of Stapes-Mobilization Operation: Report of Results and Experiences. D. Myers and B. J. Ronis. *A. M. A. Arch. Otolaryng.* 64:307-323 (Oct.) 1956 [Chicago].

The authors describe experiences with Rosen's stapes-mobilization operation, which were obtained in 161 operations on 139 patients in a period of 18 months. Sixty-five (47%) of the patients were improved, while 74 (53%) were not improved. Two patients with failure underwent a successful fenestration. No surgical difficulties were encountered because of the previous stapes operation. While a degree of proficiency can be acquired with practice on cadavers, the feel of mobilizing the stapes can be obtained only on the living patient with otosclerosis. Only rarely will the cadaver specimen give the opportunity of mobilizing a fixed stapes. At first the results may be discouraging, and, due to lack of experience, complete mobilization may not be obtained, the crura may be fractured, or the incus may be disarticulated. With regard to the selection of patients the authors say that at the present time the successful candidate cannot be predicted preoperatively. The degree of stapes fixation cannot be predicted by the preoperative audiologic survey. There has been no correlation in this series between the degree of fixation, the degree of deafness, the length of time the deafness existed, and the amount of pressure or pull needed to obtain mobilization. Patients with every degree of deafness due to otosclerosis were operated on in order to explore the possibilities of Rosen's procedure. The stapes-mobilization operation has opened a new vista in the surgical rehabilitation of the deafened patient with otosclerosis. It can restore hearing to practical or normal levels. The operation is physiologically correct, restoring the impedance-matching mechanism to normal when successful. There were no untoward complications in this series of patients.

THERAPEUTICS

Experience with a New Anticoagulant *Coumadin* (Warfarin) Sodium. D. H. Goodman. *Arizona Med.* 13:389-392 (Oct.) 1956 [Phoenix, Ariz.].

Warfarin sodium, a coumarin derivative, was given routinely to 150 patients with coronary thrombosis with myocardial infarction and to patients with other conditions requiring anticoagulant therapy, such as thrombophlebitis, phlebothrombosis, phlebitis migrans, and cerebral thrombosis. The drug can be given intravenously as well as orally. Results show that a single dose of from 50 to 75 mg. given intravenously or orally will within 24 hours induce a therapeutic hypothrombinemic response. A therapeutic hypoprothrombinemia was readily maintained by a daily dose of 10 mg. or an intermittent dose of 25 mg. at three-day intervals. Bleeding occurred in 12 patients (8%); it was manifested primarily by hematuria and was readily controlled by intravenous administration of vitamin K (Mephyton). No undesirable side-effects or toxic reactions, such as cutaneous reactions or blood dyscrasias, were observed. The contraindications to the use of warfarin are similar to those for bishydroxycoumarin (Dicumarol). Warfarin should not be given to patients with all types of purpura and other blood dyscrasias, associated with a hemorrhagic tendency; patients with liver disease; patients who recently have been subjected to surgical treatment of the central nervous system; and patients with ulcerative lesions of the gastrointestinal tract, dissecting aneurysm, renal insufficiency, and with carcinoma of the body and the tail of the pancreas associated with thromboses. Warfarin possesses properties that make it most nearly the ideal anticoagulant of all those available at present. The low cost of warfarin is a factor of particular importance in long-range ambulatory treatment. Less frequent prothrombin determinations are needed because of the smoothness of the prothrombin response and absence of cumulative effect.

Analgesic Properties of Mixtures of Chlorpromazine with Morphine and Meperidine. G. L. Jackson and D. A. Smith. Ann. Int. Med. 45:640-652 (Oct.) 1956 [Lancaster, Pa.].

Clinical observations on the enhanced effectiveness of narcotics given with chlorpromazine suggested that more complete and longer-lasting relief from pain may be expected as a result of concomitant administration of these agents. Tests were carried out on 211 patients to verify the clinical impression. It was found that, when chlorpromazine is combined with morphine, the analgesic properties of the combination are greater than those of either drug alone. The addition of chlorpromazine to 25 mg. of meperidine hydrochloride produces an analgesic response similar to that seen with 75 mg. of meperidine. Chlorpromazine administered prior to morphine increases the analgesic effectiveness of the second agent. Likewise, chlorpromazine administered prior to certain combinations of morphine and chlorpromazine appears to increase the effectiveness of the combinations.

Cobalt-Iron Therapy for Common Types of Anemia. D. C. Ausman. Journal-Lancet 76:290-294 (Oct.) 1956 [Minneapolis].

The author reports observation on 44 patients with anemia. Anemia in 10 patients, of whom 4 had arthritis, 4 carcinoma, and 2 thyroid insufficiency, responded well to cobalt-iron therapy. The comparative efficacy of iron and of cobalt-iron was studied in 18 women with iron-deficiency anemia due to menstrual blood loss or previous pregnancy. With iron alone, 12 of 18 patients improved their hematological status; 6 did not. With cobalt-iron therapy, 17 patients improved hematologically; only one did not. An additional group of nine iron-deficient anemic patients who had not received iron therapy previously were also treated effectively with cobalt-iron. Gastrointestinal conditions or dietary abnormalities were associated with anemia in seven patients. In none did iron deficiency appear to be the primary factor. In five of these patients response was poor to iron therapy but excellent to cobalt-iron, as it was in two additional patients, in whom iron alone was not used initially.

Routine use of cobalt-iron therapy offers advantages over the use of iron alone in the treatment of many common anemias seen in general practice. This is particularly true of the iron deficiency anemia occurring so often in women as a result of menstrual blood loss or pregnancy. The cobalt-iron preparation was not only more rapid and effective than oral administration of iron but was effective even in patients who failed to respond to the intravenous administration of iron. The gastrointestinal tolerance for cobalt-iron was similar to that shown for ferrous sulfate. A skin rash appeared in two patients during cobalt-iron therapy. It was not severe enough to discontinue therapy and disappeared promptly when treatment was completed.

Therapeutic Effects of Prednisone in the Treatment of Typhoid and Brucella Infections. A. Alfano and G. Amati. Riforma med. 70:1078-1081 (Sept. 22) 1956 (In Italian) [Naples, Italy].

The authors report the results obtained with prednisone in six patients with typhus, two with paratyphoid, and four with brucellosis. The ages of the patients ranged between 22 and 58 years. Treatment was started between the 6th and 25th day in patients with typhus and between the 10th and 32nd day in patients with brucellosis. Two patients with typhus had previously been treated with chloramphenicol, and one patient with brucellosis had previously been treated with aureomycin for five days. Prednisone treatment was given for from 4 to 6 days in patients with typhus and for *from 6 to* 11 days in patients with brucellosis. Patients with typhus were given 30 mg. per day, with a total dose of 90 to 110 mg., and those with acute brucellosis were given a total of 110 to 190 mg., also in doses of 30 mg. per day. The hormone was given alone to one patient with typhus and one with paratyphoid; the other patients with typhus and paratyphoid received it in combination with chloramphenicol, and patients with brucellosis received it in combination with tetracycline. Fever dropped in from 12 to 20 hours. The effect on cenesthesia was rapid and marked: euphoria ensued a few hours after the hormone had been given. Toxic symptoms and headache disappeared rapidly. The pulse and the blood pressure of patients with typhoid improved. Asthenia, profuse perspiration, and muscular pain regressed markedly in patients with brucellosis. There were no side-effects. Prednisone given in small doses has an effect superior to that of cortisone, it is less toxic, and it is particularly helpful in the therapy of infectious diseases of the septicemic type.

PHYSIOLOGY

Sex Chromatin in Oral Smears. A. D. Dixon and J. B. D. Torr. Brit. M. J. 2:799-800 (Oct. 6) 1956 [London, England].

Oral smears were taken from 98 females and 162 males between the ages of 16 months and 60 years, in an attempt to test the validity of the oral smear method as an aid in diagnosis of the chromosomal sex made on sex-chromatin findings in the nuclei of the epithelial cells from the mucous membrane of the oral cavity. Sex-chromatin was not observed in the 162 male smears examined, but in most of the 95 suitable female smears, 35 to 50% of the cells counted contained a sex-chromatin mass. Thus the chromosomal sex was determined with considerable accuracy in the persons from whom the oral smears were obtained. As experience in the examination of the smears was gained, the diagnosis of the chromosomal sex became progressively more accurate. The procedure is simple in its application and if necessary may be readily repeated.

The findings in the 260 persons confirmed the previously established well-recognized difference between the nuclei of male and female epithelial cells. The mass of sex chromatin can be positively identified only in an absolutely peripheral position in the nucleus. This probably explains why, in a proportion of cells in any smear from females, the sex chromatin is not visible. In female smears the sex chromatin was usually first seen in one of the first five cells counted. As this finding occurred with great regularity it was decided that a count of 25 cells was quite adequate for sex determination. This is of particular significance in young infants in whom it may be difficult to obtain smears in which more than 25 cells fulfilling the essential criteria can be seen. These findings may help to standardize the method and insure correct diagnosis.

Physical Activity and the Diet in Populations Differing in Serum Cholesterol. A. Keys, J. T. Anderson, M. Aresu and others. J. Clin. Invest. 35:1173-1181 (Oct.) 1956 [New York].

Data on total serum cholesterol are presented for samples of men, classified by age and physical activity, in Minnesota; Malmö, Sweden; Bologna, Naples, the island of Sardinia; and three ethnic groups in Cape Province, South Africa. Data on the cholesterol in the beta lipoprotein fraction in the serum are presented for some of these groups. Differences in physical activity do not explain the large differences in serum cholesterol found when groups with different dietary habits are compared. Within some populations there is a tendency for men in heavy manual labor to have somewhat lower serum cholesterol values than the other men in the population. Among the Bantu, who show this tendency most prominently, it was found that the men in heavy work consume diets lower in fats than the other Bantu, and there is other evidence pointing to a general tendency for the composition of the diet to be related similarly to the habitual level of physical activity. It is concluded that the habitual diet, and especially its fat content, has much more influence than the physical activity, per se, on the concentration of total cholesterol and beta lipoprotein cholesterol in the blood serum.

BOOK REVIEWS

Dermatology. By Donald M. Pillsbury, M.A., D.Sc., M.D., Professor and Director of Department of Dermatology, University of Pennsylvania School of Medicine, Philadelphia, Walter B. Shelley, M.D., Ph.D., Associate Professor of Dermatology, University of Pennsylvania School of Medicine, and Albert M. Kligman, M.D., Ph.D., Associate Professor of Dermatology, University of Pennsylvania School of Medicine. Cloth. $20. Pp. 1331, with 561 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1956.

This new textbook by men active in basic dermatological research has a fresh, critical approach and an emphasis on fundamentals that makes it the best single volume on dermatology available to students and practitioners. It is not intended to replace the more encylopedic works for the specialist, but many of its sections should be of interest to dermatologists as well, particularly the brief, readable reviews of basic science, the objective evaluations of current therapy, and the reasonable discussion of psychocutaneous medicine. The authors have devoted about 20% of the book to reviews of the anatomy, physiology, pathology, bacteriology, mycology, parasitology, allergy, and genetics of the skin. They justify this emphasis by pointing out that the skin is usually given short shrift in preclinical teaching, leaving students and clinicians with little understanding of its normal functions and basic pathological patterns. All of these reviews have a conversational tone and a practical slant that should assure greater readership than usual for material of this type. The outline of basic patterns of pathological conditions in dermatology is particularly concise, logical, and comprehensive.

Another 10% of the book is devoted to methods of dermatological diagnosis. Included in this section are chapters on regional diagnosis, pediatric and geriatric dermatological diagnosis, and dermatology in the tropics. In addition, the characteristic distributions of several common skin diseases are described and illustrated, and the basic types of skin lesions are defined and pictured in excellent black and white photographs. The next 5% of the book deals with the general principles of dermatological therapy, including topical and systemic measures. The discussion of the use of ionizing radiation in dermatology is ultraconservative, but this is preferable in an introductory text. The remainder of the book deals with the diagnosis and therapy of individual dermatoses. The material is presented in a readable, informal manner, and definite opinions and guidance are given throughout. The discussions of cause and therapy are refreshingly critical. The authors tend to reject much traditional therapy that has not been proved by controlled study. They are perhaps too pessimistic about the treatment of acne and superficial fungus infections and too hasty in discarding ammoniated mercury as an antibacterial agent. Detailed descriptions of histopathological changes in individual dermatoses are not given, but the authors indicate those diseases in which skin biopsy is helpful or essential. All in all, this is an important new book that should have many future editions.

Venous Return. By Gerhard A. Brecher, M.D., Ph.D , Julius F. Stone, Professor of Physiology, Department of Physiology, College of Medicine, Ohio State University, Columbus. Cloth. $6.75. Pp 148, with 55 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 99 Great Russell St., London, W.C.1, England, 1956.

This is an excellent presentation of a difficult and sometimes controversial subject. It is clear, readable, and thorough. It was not within the scope of this short monograph to survey the entire field of venous physiology. Instead, the author has confined himself in the main to analysis of the several major mechanisms' that determine venous return to the heart. Much of the information presented is recent, some of it previously unpublished and derived from the author's experiments that used high-fidelity methods of measuring venous flow. There is an historical review, two chapters on basic venous hemodynamics, and a review of various methods, old and new, of measuring blood flow. Through the use of profuse illustrations of good quality, and of a concise text, the present status of the roles of ventricular ejection, the respiratory pump, systolic ventricular attraction, the muscle pump, venomotor activity, and diastolic ventricular suction in return of blood to the heart is brought into sharp focus. There is particular attention given to the author's investigations on the diastolic ventricular sucking effect. Of special interest to thoracic surgeons are a review of the effect of artificial respiration on venous return, a short chapter on venous hemodynamics in the presence of lesions of the cardiac valve, and a chapter on venous return during cardiac surgery. A helpful feature of the book is the inclusion of a brief summarizing statement of each major topic. The bibliography is complete and the index good. As stated in the foreword, written by Dr. Wiggers, "This monograph is the only current one that gives a comprehensive analysis of the determinant of venous return and its adaptation to cardiac output based on experimental measurement of venous flow. It should be welcomed alike by laboratory investigators and clinicians who must at all times be alert to avoid procedures that interfere with natural factors favoring venous return"

Peripheral Vascular Disorders. Edited by Peter Martin, V.R D, M Chir, F.R.C.S., Surgeon to Chelmsford and Billerecay Hospitals, Essex, England, R. Beverley Lynn, M.D., F.R.C S., Assistant Professor of Surgery and Markle Scholar, Medical College, University of Saskatchewan, Saskatoon, J. Henry Dible, M.B., LL.D., F.R.C.P., Director of Pathology, Postgraduate Medical School, London, and Ian Aird, Ch.M., F.R.C.S , Professor of Surgery, University of London, London. Cloth. $20. Pp. 847, with 450 illustrations. E. & S. Livingstone, Ltd., 16 and 17 Teviot Pl , Edinburgh 1, Scotland, *Williams & Wilkins Company, Mount Royal and Guilford Aves*, Baltimore 2, 1956.

This comprehensive and lucidly written volume is the combined effort of nine contributors, five of whom either are surgeons or are working in related fields. Three are research workers in the basic sciences, and one is a radiologist. The plan used in writing this book is a reflection of the interests of the authors, with the medical point of view conspicuously absent. The first portion of the book is devoted to the basic anatomy and physiology of the peripheral vessels and the laboratory and clinical methods of studying the circulation. The role of the sympathetic nervous system and its innervation of the vascular tree are stressed. Numerous diagrams and photomicrographs help to elucidate the text. The section also contains an excellent chapter on the radiology of peripheral vascular disorders. Included are descriptions of the results of soft-tissue x-ray technique, arteriography, and venography. The various pathological alterations are profusely illustrated by instructive photographs of high quality.

The remainder of the volume deals with the pathology, clinical manifestations, and treatment of diseases of the arterial, venous, and lymphatic systems. A good portion of this section is devoted to pathological alterations, particularly those of atherosclerosis and thromboangiitis obliterans. Gross changes in the arterial tree are graphically depicted through the use of roentgenograms of amputated limbs in which the arteries and their branches have been outlined by a radiopaque medium Numerous photomicrographs are used to show the different microscopic changes in the lumen of the vessels. With regard to treatment, throughout the text emphasis is placed on surgical therapy. The indications and contraindications for sympathectomy are presented in much detail. The last chapter is devoted entirely to descriptions of the various operations used in peripheral vascular disorders. Included are relatively new methods, such as the use of venous and arterial transplants, as well as the older conventional techniques. The various steps are presented in sufficient detail to be of value to the surgeon.

Even superficial perusal of the text reveals evidences of inadequate proofreading and editing. There are numerous mistakes in grammar and typographical errors, and references to subject matter elsewhere in the volume or to figures are not always accurate. Different methods of presenting the extensive bibliographies are used in the various chapters. In some instances photographs are duplicated; for example, figure 359 on page 652 is also presented as figure 385 on page 709. Figures 313 and 314 appear to be the same except that one is in color and the other, in black and white. This volume should be of real value to the specialist in peripheral vascular disorders, particularly the vascular surgeon. Much of the detailed subject matter, however, is not presented in a manner that permits ready clinical applicability to the problems of the general practitioner.

QUERIES AND MINOR NOTES

PALLOR ON EXPOSURE TO COLD

To the Editor:—*A 30-year-old man has severe erythralgia of the hands, face, and feet on exposure to temperatures below 50 F. He is in good health and has no history of previous frostbite. Is there any effective treatment or prophylactic measure?* *Charles A. Lichty, M.D., Shelbina, Miss.*

Answer.—The use of the designation "erythralgia" is somewhat confusing, but it is presumed that it is used to designate pallor on exposure of the skin to cold. Associated with pallor or following the pallor there may be varying degrees of cyanosis and rubor. The diagnosis, therefore, may be Raynaud's syndrome. This is quite commonly associated with scleroderma, and careful search should be made for scleroderma, although there is no satisfactory treatment for this condition. The treatment for Raynaud's syndrome is purely symptomatic and, in many instances, unsatisfactory. Glyceryl trinitrate (nitroglycerin) ointment applied to the fingers is sometimes helpful. One of the ganglionic blocking agents commonly used in the treatment of hypertension, such as methenamine (hexamethylenamine), may be beneficial. Sympathectomy, which causes symptomatic denervation of the skin of the face and hands, is helpful in preventing episodes of discoloration on exposure to cold in approximately one-half to two-thirds of patients who are operated on. Sympathectomy of the lower extremities is almost uniformly curative in preventing episodes of discoloration of the feet on exposure to cold.

ADRENALECTOMY FOR CANCER

To the Editor:—*Has there ever been a reported case of cancer cured by adrenalectomy after other methods have failed? Since cancer patients who have undergone bilateral adrenalectomy should receive substitution therapy, what preparation is the best and at what dose? What precautions should be observed in such adrenalectomized patients? How should one observe and maintain electrolyte balance? Would the use of 5% dextrose in 500 cc. of lactated Ringer's solution be contraindicated? How long do such cancer patients live after bilateral adrenalectomy? How do you explain the fever that occurs in such patients who had undergone adrenalectomy and who apparently show no infection?* *M.D., Philippines.*

Answer.—Cancer of the adrenal has been cured by adrenalectomy. The purpose of bilateral adrenalectomy in the patient with advanced cancer has been to control the disease and to promote a remission of its painful and systemic manifestations. Although it has been tried in other types of cancer, the successful remissions have been in the "hormone dependent" tumors of the breast and prostate. Scott and Huggins in 1945 produced a remission by this procedure in a patient with advanced carcinoma of the prostate, but since cortisone was not available they were limited in their substitution therapy. The operation has been performed by many investigators since this compound has become readily available. Hundreds of patients with advanced carcinoma of the breast and prostate have had bilateral removal of the adrenals with remission of their cancer lasting from a few months to many months. None has been reported cured.

The success of the operation depends on adequate substitution for compounds that were supplied by the adrenals and are necessary to maintain the electrolyte balance and other metabolic functions without reintroducing compounds that will promote the growth of the tumor. Exactly what the compound, or its metabolic products, will do to the metabolism of a tumor is not predictable at the present state of knowledge. In the selection of an adequate adrenal substitute, it is necessary to have both an electrolyte controlling hormone and a metabolism regulating effect. Cortisone has the advantage of having a satisfactory balance between these two functions, and, when the patient receives 50 to 75 mg. of cortisone and 4 to 5 gm. of sodium chloride a day, he can be maintained indefinitely, as long as the necessary precautions are observed.

The precautions to be observed are the same as in patients with adrenal cortical hypofunction (Addison's disease). Because the treatment of the patient with cancer requires the minimum maintenance dose of cortisone in order to be most effective, the dosage will have to be worked out for the individual patient. Consequently the resistance to stress and infection is very low and care should be taken to reduce these factors as much as possible. The patient should be instructed that the necessity of taking the cortisone is not only important to his well-being but also to his life, that if he is nauseated and unable to take it by mouth it should be taken by injection, and also that the use of mineral oil and other nonabsorbable fat-soluble compounds will carry the adrenal compounds through the intestinal tract without being adequately absorbed. The serum sodium and potassium levels should be checked at regular intervals and, as it is established that adequate replacement therapy is being given, the interval can be lengthened. The urine output volume is a good index of adequate replacement and will be of normal quantity when the patient is receiving enough cortisone to excrete potassium and will keep the serum potassium level within a normal range. The serum sodium level will drop on a low dosage of cortisone unless the sodium chloride intake is increased. A low serum sodium level and high serum potassium level indicates inadequate dosage. A high serum sodium level and low serum potassium level indicates over-replacement. It is worth while to watch also blood nonprotein nitrogen level, carbon dioxide-combining power, and serum chloride, phosphorus, and calcium levels. An elevated nonprotein nitrogen level and lowered carbon dioxide and increased chloride and phosphorus may be present if cortisone dosage is inadequate and renal output is very low for a long time, but this should be reflected first in serum sodium and potassium levels. The serum calcium level rises when the limit of the kidney to excrete it is passed. When this point is reached it is usually due to the freeing of excess calcium from the bones by the invasion and destruction by the cancer and indicates an increase in activity of the malignant cells. The use of Ringer's solution would depend entirely upon the problem that has to be treated, and if the problem required the elements in this solution it would be safe to give it. There is certainly no direct contraindication because of adrenalectomy. During the immediate postoperative period, when the cortisone dosage is usually high and urine output is large, this solution may be very helpful.

The length of time a patient lives after bilateral adrenalectomy is not limited by the operation or the substitution regimen. The cancer continues to grow but the rate of growth is much slower. It is apparently the shrinkage of each cell with release of local pressure that produces the remission of the pain and the systemic manifestations. The remission is often enough to permit many months of useful and pain-free life. Again the purpose of the operation is to withdraw a substance on which tumor growth is dependent. The tumor may regress for a time and then grow again when it finds other metabolic pathways that are not hormone-dependent.

TREATMENT OF REITER'S DISEASE

To the Editor:—*Please give an opinion concerning the treatment and prognosis of Reiter's disease.*

M.D., Pennsylvania.

Answer.—A treatment program for a patient with Reiter's disease should be planned only after giving careful consideration to the character of the disease in the individual under consideration. The disease varies widely in its manifestations from one person to another. In some instances the skin eruption is severe; exfoliating and hyperkeratotic lesions appear about the

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

palms, soles, and even on the face and trunk; sometimes fever is present; and the joints may be extremely painful and swollen and the patient seriously debilitated, unable to take nourishment properly, and in need of considerable nursing care. In others, the disease is much less severe; the skin eruption may consist only of minor inflammatory changes about the palms and soles, with a few scattered lesions elsewhere on the body; conjunctivitis may appear and disappear from time to time; and the articular changes may be only slightly troublesome. In some instances the disease runs a self-limited course, all symptoms subside under the influence of careful nursing, and very little additional treatment may be required. In others, the disease progresses inexorably, producing the most intensive articular deformities accompanied by destructive changes such as may be seen in severe rheumatoid arthritis.

During acute early stages of the disease, supportive treatment should be devised to fit the particular situation in the patient under consideration. Often, complete bed rest is essential during the acute stage of the disease. If the joints are violently inflamed, splints and other supports may need to be devised in order to prevent needless pain from motion. When severe exfoliative and hyperkeratotic skin lesions are present, daily soaks or wet packs using dilute potassium permanganate solution of 1 to 10,000 aids in removing the crusts and subsequently 5% ammoniated mercury ointment may be applied to the sites of the skin lesions. For treatment of urethritis, hot sitz baths may be helpful. Irritating secretions from conjunctivitis should be washed out with saturated solutions of boric acid and mild boric acid ointment applied to the conjunctival margins. During severely painful phases of the disease, salicylates may aid in controlling the discomfort, and in some instances small doses of codeine or other narcotic may be required.

During recent years increasing experience with steroid compounds in treatment of patients with Reiter's disease has been acquired in many medical centers, and, in general, those who have employed steroid therapy have had good results. If steroids are used, prednisone or prednisolone in doses of 20 to 30 mg. daily should be given in divided doses as an initial step. Thereafter, this dose may be gradually reduced as symptoms come under control. In some instances, continued administration of steroids may be required for several months and in this event usual precautions should be taken to prevent gastric irritation by means of antacids, to prevent edema formation by reducing salt intake, and to prevent or reduce the possibility of other Cushingoid phenomena by reducing the dose as rapidly as possible in relation to the response of the patient.

STRONGYLOIDES INFESTATION

To the Editor:—*A 45-year-old woman has had Strongyloides infestation of her alimentary tract for 10 years. She has taken all possible precautions against recurrent reinfestation, and none of six immediate family members have stools positive for Strongyloides; yet she never has had a stool specimen free of viable worms or occult blood. Previous treatment included hexylresorcinol, piperazine citrate, tetrachlorides, gentian violet, and even weird concoctions advised by neighbors and fringe practitioners and by herbalists. She now has marked secondary microcytic, hypochromic anemia and feels tired and listless. I have done complete hematological studies, gastrointestinal tract series, and proctoscopic and gastroscopic examinations, which prove normal except for anemia. She has had three courses of gentian violet, enseals (2 ½-grain [30 mg.] capsules three times a day after eating) for 21 days each time. No intact enseals have been found on repeated search of stools, and yet stools continue to contain both live and dead Strongyloides. Can you suggest a better treatment?*

M.D., California.

Answer.—The adult Strongyloides worms usually are embedded in the mucosa and submucosa of the small intestine. They are small, the female measuring about 2.2 mm. Eggs, which resemble those of hookworm, hatch in the tissues or intestines, liberating the rhabditiform larvae that are found in the stool. After discharge from the body the larvae may establish a free living cycle outside the body, or, if conditions are unfavorable, the rhabditiform larvae may be converted into the infective filariform larvae. This infective form penetrates the skin of man, gets into the capillaries, takes the heart-lung route, ascends the respiratory passages to reach the esophagus, and passes down into the stomach and intestine. Some worms may migrate into the pulmonary tissue and develop there, giving rise to larvae in the sputum. The complete cycle may take place in one host, resulting in internal reinfection. In these cases the rhabditiform larvae metamorphose into filariform larvae within the intestine or on the perianal skin. These infective larvae penetrate the mucosa of the lower intestine, or the perianal skin, resulting in hyperinfection. In these cases the infection is not self-limited but continues to build up within the body in the absence of reinfection from the outside. Also the infective larvae may be ingested with uncooked vegetables and gain entrance to the body through the mucous membranes. Usually eosinophilia is present and, when absent, is a poor prognostic sign. The diagnosis is established by finding the characteristic larvae in the stool. Sometimes they are found only in material aspirated from the duodenum.

Eradication of this worm is difficult. Medicinal gentian violet is recommended but often gives unsatisfactory results. For those who do not respond to the oral therapy with gentian violet duodenal intubation is recommended. The patient should be in the hospital. The day before treatment the patient is given a liquid diet, and early next morning an enema to clear the lower part of the intestine. Then pass the duodenal tube, making sure it is in the duodenum, and inject 25 cc. of a 1% aqueous solution of gentian violet medicinal. In chronic cases of long duration this treatment will have to be repeated when the larvae in the tissues become adults. Twenty-eight days are required from the entrance of the filariform larvae through the skin to the appearance of rhabditoid larvae in the stool. In extraintestinal infections the intravenous route is recommended (25 ml. of sterile 0.5% aqueous solution of gentian violet medicinal). Diethylcarbamazine (Hetrazan) is useful in some refractory cases (2 mg. per kilogram of body weight three times daily for 10 to 20 days; total dose, 4 to 8 gm.).

PURE NEPHROSIS

To the Editor:—*A 9-month-old boy presents the picture of nephrosis. He had never been ill until he was 7 months of age, when he developed a head cold with ear, nose, and throat involvement, lasting three days, during which time his temperature reached 105 F (40.5 C) (rectal). He was treated with penicillin injections and oral medication, presumably sulfonamides. One month after his illness, the parents noted some puffiness of the eyes, followed by swelling of the feet, abdomen, hands, and face. The baby was irritable, but not feverish. There was no anuria or rusty, discolored, or grossly bloody urine. Physical examination showed only generalized edema. Blood pressure was 98/68 mm. Hg. Urine consistently showed albumin. Treatment has consisted of therapy with prednisolone, Diamox, and Thorazine. What is the prognosis for a baby who has this condition, and what future treatment is recommended?*

Charles L. Concklin, M.D., Corpus Christi, Texas.

Answer.—From the data submitted, it seems that the child has "pure nephrosis." If this is the case and no other systemic disease is involved, then the prognosis for this patient with nephrosis is similar to that for patients in older age groups: excellent for recovery, unless progressive renal failure ensues. Steroid treatment seems entirely adequate. It is not unusual to use prednisolone initially, 1 mg. per pound of body weight daily for two to four weeks until diuresis is complete and the patient has been free of proteinuria for approximately one week. This is followed by a plan of long-term steroid therapy that is satisfactory for the patient situation. Usually, the same dose of prednisolone is used three consecutive days of each week. This is continued for 9 to 12 months, as long as proteinuria is controlled. Therapeutic doses of a broad-spectrum antibiotic are used during the daily initial therapy; none are used during the period of intermittent steroid administration unless infection occurs. Diamox is not effective in the edematous stage of this disease.

TOXICITY OF XYLENE (XYLOL)

To the Editor:—*Xylene (xylol) is being used in a certain plant. What test can be depended on to determine the safe concentration of xylene in air? What are the effects of intoxicating levels and how long may workers stay in this environment? Are the effects of xylene cumulative? Should routine testing be done on workers?*

William M. Vest, M.D., Ukiah, Calif.

Answer.—Tests for the quantitative determination of xylene (xylol) levels in an industrial plant are practical but difficult. The maximum acceptable concentration of xylene is 200 ppm of air for an eight-hour work period. The vapors of xylene are so irritating to the eyes that workers usually will not work in any significantly high concentration. Xylene is the homologue of benzene and toluene but is far less toxic than benzene and perhaps of nearly the same toxicity as toluene. There may arise both acute and chronic damage. In the acute stage and in mild cases, attention should be paid to complaints of excessive fatigue, dizziness, palpitation, mental confusion, numbness in extremities, tremors, dyspnea, and anxiety. In more severe poisoning, unconsciousness may be brought about, and this, if relieved, may be followed by excitment, gastrointestinal pains, headaches, insomia, and formication; nausea and vomiting may appear. In the chronic form all acute manifestations may persist with added severity and persistence of symptoms referable to the nervous system, including stupor and paresthesia. A common complaint is that of persistent gastrointestinal disturbance. Hypotension may appear. The damage from xylene is less reflected in the cellular elements of the blood than is benzene, although low red blood cell counts may appear. Leukopenia, which is fairly characteristic of benzene poisoning, rarely occurs from the action of xylene. A relative lymphocytosis is the rule. In general, not too much is to be expected from blood cell counts in suspected xylene poisoning. At least in the past, some commercial xylene has proved to contain some benzene, which greatly adds to the prospect of injury. Recourse should be had to more adequate presentation, such as is found in Browning's "Toxicity of Industrial Organic Solvents" (Medical Research Council, Industrial Health Research Board report no. 80, ed. 2, London, Her Majesty's Stationery Office, 1953).

SEDIMENTATION RATE AFTER SPLENECTOMY

To the Editor:—*What do you consider a normal sedimentation rate for a person who has had splenectomy?*

J. M. Hesser, M.D., Benson, Ariz.

Answer.—The sedimentation rate depends on the type of tube in which the determination is carried out, and without knowing what method the inquirer uses no values can be given. The sedimentation rate appears to be dependent on several factors, i.e., the level of the total plasma proteins and the relation of the various fractions to one another; the presence of either anemia or polycythemia. A splenectomy in itself should not significantly affect the sedimentation rate. If the patient has a normal red blood cell count and if there is no underlying chronic disease, one would expect the sedimentation rate to be normal.

MUSCULAR DYSTROPHY

To the Editor:—*A 21-year-old Chinese man has atrophy of two years' duration of the muscles of both arms, thighs, and shoulders, including the pectoralis major and minor muscles, supraspinatus, infraspinatus, teres minor, and rhomboids. There is still some function of the deltoid muscles. The muscles of the forearms, hands, legs, and feet are still intact, and of normal dimensions. The upper extremity has "Popeye" configuration: no biceps muscles but full muscular forearm. What therapy would be more specific than supportive?*

Alfred O. Mazat, M.D., Singapore.

Answer.—The condition described is in all probability a scapulohumeral type of muscular dystrophy of Déjerine-Landouzy variety. Mention is not made of facial involvement, nor is any history of familial incidence given. These two phases of the disease should be investigated, since facial involvement is minor but frequent in these patients in many cases, and very minor involvement of siblings and other members of the family may be elicited with careful examination. Although isolated cases of this type of muscular dystrophy can be found, the more common type is hereditary and is transmitted as a dominant. The only diagnosis that seems to be possible, other than the above, is a chronic myositis involving both girdles, but the distribution of atrophy described in this case is most unusual for such a condition. There is no accepted form of treatment for this condition. Many drugs and preparations have been used, and the most popular at the present time is aminoacetic acid (glycine), in dosage of 10 to 20 gm. per day. This is said to retard the progression of the disease in some cases and in others has shown some beneficial effect, but never of striking character. Another treatment that has had some popularity is the administration of vitamin E in dosages between 100 and 600 mg. daily. This also is of doubtful benefit, although controversial reports have been made on the subject. Still another controversial method of treatment is that of a combination of nutritional factors such as vitamin B_{12}, folic acid, and a mixture of amino acids. The latter have been administered mostly in the form of a casein hydrolysate, although liver hydrolysates have been advocated also. All of these nutritional supplements are of doubtful specific effect.

SWADDLING AND SHORT STATURE

To the Editor:—*Asiatics, Eskimos, Laplanders, and Greeks have short stature and they swaddle their babies for the first 12 to 15 months. To what degree is swaddling, or are other factors, responsible for short stature?*

S. Partheniou, M.D., Poros, Greece.

Answer.—The practice of swaddling infants is widespread. Although frowned on by psychiatrists and pediatricians because of retarding behavioral development and possible effects on the personality of the child, it cannot be implicated in the suppression of full stature growth. Swaddling is a procedure found among both tall and short peoples. Many factors have been implicated in the development of stature, such as climate, weather, cultural practices, nutrition, and race. Of all these, only ethnic extraction and nutrition are thoroughly documented. In discussing race as a factor, it should be understood that the concept as presently used is a dynamic one. Race is no longer considered a static type, but a population concept, statistically defined and undergoing constant change in the proportions of different genetic determiners. The influence of nutrition is well documented in studies of European, Polynesian, and Mexican immigrants to the United States. Where nutrition is improved, there is a consistent increase in stature from one generation to the next, with no change in the genetic composition. This does not mean that one can increase stature indefinitely through improved diet but only that the depressing effect of poor nutrition can be negated by good diets within racial limits.

ADENOID TISSUE IN ADULTS

To the Editor:—*A 24-year-old woman had a tonsillectomy and adenoidectomy in March, 1955, after which there was persistent clear mucoid drainage from the region of the adenoids for one year. Secondary adenoidectomy has likewise failed to eliminate this drainage. Incomplete epithelization was considered as the cause. Various medicaments, including Lugol's solution, thyroid, dilute iodine in glycerine, and estrogenic nasal drops have been tried. Could you outline a regimen that might eliminate this disconcerting problem?* M.D., Ohio.

Answer.—Adults generally do not have adenoids. By adenoids is meant the diseased and hypertrophied pharyngeal tonsil, as distinguished from the faucial tonsil. It is true that many individuals do have remnants of lymphoid tissue in the area; this so-called adenoid "rest" as a rule is symptomless. If there were persistent drainage before the operation, it could have been due to one of the following conditions. 1. The remnant of pharyngeal tonsil may have had a persistent medial cleft that tended to seal over; from time to time this could open and empty itself. 2. The other condition, about which there is some disagreement, is generally termed nasopharyngeal (Thornwaldt's) bursitis. This nasopharyngeal cleft is said to spring from (*a*) notochordal contact with the nasopharyngeal mucosa, (*b*) Rathke's pouch, or (*c*)

Seessel's pocket. Such a mucosa-lined pocket can be diagnosed by careful nasopharyngoscopy, and, if present, needs to be curetted under direct inspection via the Yankauer nasopharyngoscope or by elevation of the palate by means of a Jackson soft palate retractor. Not to be forgotten are the ordinary causes of postnasal drip, which include all those irritating mucous membrane agents and conditions, so well described by Proetz (*Ann. Otol., Rhin. & Laryng.* 54:739, 1945). In addition, this case calls for ruling out of posterior cell sinusitis and nasal allergies. For therapy it is suggested that Proetz' article be consulted.

CYSTITIS

To the Editor:—*An unmarried woman, 66 years of age, has had frequency of micturition, nocturia, burning and smarting on urination, decreased bladder capacity, and pyuria for the past three years. She has been given numerous medicaments, with no benefit. Candida krusei fungus has been isolated on cultures. What would be the appropriate treatment?*

H. W. Waters Jr., M.D., Montgomery, Ala.

Answer.—Candida krusei is generally regarded as a saprophyte, and there is little or no evidence that it causes infection when found in the urinary tract. The bacteria commonly found with cystitis may be obscured on culture by the Candida (Monilia) infection. It would be advisable, therefore, to make repeated cultures as well as smears of the urine in order to determine the existence of etiological bacteria, and antibiotics should be administered according to the type of bacteria found. Involvement of the bladder with Candida often responds to lavage with a solution of methylrosaniline chloride (gentian violet) (1:1,500) or a weaker solution of acriflavine. A new drug, nystatin, has been found to be of value in treating monilial infection of the urine. It may be used both orally and as a medium for irrigation of the bladder. When used for irrigation, a solution made by dissolving one tablet of nystatin in a liter of water may be tried. Injections of Tritheon (2-acetylamino-5-nitrothiazole) also have been of value in some cases. It should be remembered that Candida infection is usually of vaginal origin, and there are many preparations that have been used locally to eliminate vaginal infections, with variable results. No mention has been made of preliminary complete urologic examination, including cystoscopy, catheterization of the ureters, and bilateral pyelography or urography. This should, of course, be done to exclude evidence of pathological conditions in the urinary tract.

INSULIN TEST AFTER VAGOTOMY

To the Editor:—*What is the insulin test as used in gastric surgery and what are the principles involved?*

M. D., New York

Answer.—The insulin test, as used in gastric surgery, depends on the discovery by Carlson and Bulatao and Wolff that a profound hypoglycemia produced by the injection of insulin stimulates the vagus centers, arousing impulses in the vagus nerves that excite the stomach to increased motility and increased gastric secretion. On the recommendations of Hollander, surgeons have made use of this physiological test to determine whether all of the vagus fibers to the stomach have been divided in the vagotomy operation. The test may be performed as follows: In the morning, with the stomach empty, the gastric content is aspirated by nasogastric suction every 10 minutes for one-half an hour to establish the control gastric secretion. The samples of gastric juice are collected separately and titrated for free hydrochloric acid with use of Töpfer's reagent. Fifteen units of regular insulin are then given intravenously and aspiration of the gastric content continued every 10 or 15 minutes for a 90-minute period. If the vagus nerves to the stomach are present, the first one or two samples of gastric juice removed may show less than the normal concentration of free hydrochloric acid but the sample collected at 20 minutes or ½ hour will usually display an increased concentration of acid, which becomes more marked at 40, 50, or 60 minutes after the administration of the insulin. The secretory response is roughly proportional to the symptoms of hypoglycemia that develop. In a patient whose vagus nerves have been completely divided, the concentration of acid in the samples of gastric juice aspirated during the hypoglycemic period does not exceed that of the control.

WESTERGREN SEDIMENTATION RATE TECHNIQUE

To the Editor:—*Do you know the method of correction of sedimentation rates for anemia when done with the Westergren technique (20 cm. column of blood)? The only correction chart I can find is that which pertains to the Wintrobe method.*

M.D., New York.

Answer.—The effect of the concentration of red blood cells on the sedimentation rate determined by the Westergren method has been studied by Ham and Curtis (*Medicine* 17:447, 1938). When the specified anticoagulant, as described below, is used in the Westergren method, the sedimentation rate is influenced relatively little by changes in the concentration of red blood cells. If other anticoagulants such as heparin or dry oxalate mixture are used, the effect of the concentration of red blood cells is large, and there is no satisfactory method for correction. The following details are suggested for the Westergren method. The Westergren "tube" is a pipet filled from the bottom. It is 300 mm. in length and 2.5 mm. in internal diameter, is graduated from 0 to 200 mm., and contains about 1 ml. The anticoagulant is an aqueous solution of 3.8 gm. of sodium citrate per 100 ml.; 0.2 ml. of the anticoagulant is added for every 0.8 ml. of whole blood, making a final concentration of 760 mg. of sodium citrate per 10 ml. of mixture and a dilution of 20% of the blood with an aqueous solution. The citrated blood is mixed and drawn up into the Westergren tube, which is then placed vertically in a stand, of special construction, that closes the bottom of the pipet by a rubber stopper and holds the tube firmly against the stopper by means of a spring. The depth of settling of the top of the red-blood-cell column is measured at the end of one hour. The author reports that the normal range for men is 1 to 3 mm. and for women, 4 to 7 mm. in one hour.

MALINGERING DURING AUDIOMETRY

To the Editor:—*What procedure is recommended for the detection of malingering when one is testing a patient for acuity of hearing with an electric audiometer?* *M.D., California.*

Answer.—The Lombard test, for total bilateral deafness, is a loudness-balance type of test, and the method of testing is generally to have the patient read out loud continuously while you increase the intensity of the sound. It will be noted that, depending on whether you are lowering or raising the intensity of the sound, the patient's voice will increase or decrease in volume. This can be done either as a unilateral or as a bilateral test. It is reliable, and the patient cannot feign this.

The repeated threshold test consists of retesting the patient at frequent intervals, that is at different times. It is difficult for the patient to remember from time to time at what frequency he was unable to hear, and in that way differences in decibel loss will vary, and one will be able to ascertain the malingering.

The swinging tone and voice test uses pure tones, instead of the masking apparatus, and is similar to the loudness-balance test.

TOXICITY OF PENTACHLOROPHENOL FUMES

To the Editor:—*An 80-year-old man with inactive, moderately advanced pulmonary tuberculosis has been painting his boat in a partially closed room with a liquid wood preserver, the base of which is pentachlorophenol. After a few hours he observed that his cough had completely abated; he remained free from cough for a number of days, after which time the cough gradually returned to its former intensity. Despite the caution on the label, he deliberately inhaled further fumes of this phenol preparation and again experienced an abatement of his cough. What is the toxic effect of continuous inhalation of fumes containing pentachlorophenol, particularly on the kidneys and liver?*

R. S. Anderson, M.D., Erie, Pa.

Answer.—It is not remarkable that pentachlorophenol appears to exert mild anesthetic properties, since many phenolic bodies do. The use described in the query may not be condoned at the present time. This substance is a known irritant for skin and mucous membranes and is believed to possess active allergenic properties. A 1% solution may provoke an acute dermatitis. When mildly heated, the vapors produce a pungent and irritating odor. Exposure to solutions is believed to be followed by skin absorption, while only scant experience with reference to inhalational effects has developed. It may be believed that, apart from local damage, the eventual severe damage may be to the circulatory system, liver, and kidneys. It is not known that any substance chemically related to pentachlorophenol is safe for use as a pulmonary sedative.

AUTHENTICATION OF VACCINATION CERTIFICATES

To the Editor:—*When there is no public health official available in the area, who is authorized to authenticate an international certificate of vaccination? Why is this second certification by a public health official necessary?*

M.D., Illinois.

Answer.—In addition to any local health officer, the certificate may be authenticated by a state health officer or an officer of the Public Health Service. The prospective traveler need not appear in person but may mail the certificate enclosing a self-addressed envelope. Health officers who do not have an official stamp to authenticate international vaccination certificates are requested to have a stamp made that includes the term "health officer" and the name and address of the health department. This stamp is required to attest to the signature of the immunizing physician, or physicians, affixed on the smallpox and cholera vaccination certificates entered in the "International Certificates of Vaccination" form. No certificate is valid without the stamp of a "health department." Public Health Service officers and medical officers of the Department of Defense will continue to use the seal of their respective service to authenticate these certificates.

Health officers of local and state health departments are required to authenticate smallpox and cholera vaccination certificates for the purpose of determining that the vaccinator is a practicing physician in the area, thereby reducing the possibility of certificates being issued by unauthorized persons. Health officers may also authenticate certificates issued by physicians in other sections of the United States if there is a means of checking the vaccinator's name, such as through reference to the American Medical Directory. Certificates issued at facilities of the Public Health Service, the Department of Defense, and designated yellow fever vaccination centers carry the stamp or seal approved for their use.

PHLEBITIS AFTER SKIING

To the Editor:—*A patient came down with acute iliofemoral thrombophlebitis after strenuous skiing. It has occurred to me that this may not be an uncommon complication among all skiers, with or without fractures. Are there statistics available of phlebitis among skiers, either in the calf or in the thigh?*

Jesse Appel, M.D., Kew Gardens, N.Y.

Answer.—A review of the literature and inquiries addressed to several other vascular surgeons as well as to numerous doctors who attend New England ski areas reveal no cases of deep phlebitis secondary to skiing. This may be due to the fact that this sport attracts healthy young participants. However, phlebitis could be caused by skiing either directly from trauma, such as fractures or muscle contusions, or indirectly from effort. The crouched skiing positions, causing angulation of the deep veins at the knee and groin in association with violent muscle contractions, could produce a tear of a valve with resultant thrombosis. Such phlebitis must be more common than is realized, and physicians may not be reporting their cases. To clarify this situation, would any physician who has observed or treated such cases kindly send a brief report to John J. Byrne, M.D., Director, Third (B. U.) Surgical Service, Boston City Hospital, 818 Harrison Ave., Boston 18.

TESTING FOR GLYCOSURIA

To the Editor:—*What is the present acceptability of the Eli Lilly product Tes-Tape as a definitive test for glycosuria?*

M.D., Arizona.

Answer.—To all intents and purposes, the product referred to gives a positive reaction only in the presence of glucose. It is highly satisfactory for determining the presence or absence of glycosuria and hence would seem to be ideal for screening purposes. However, it is considerably more sensitive than the commonly used copper reduction methods, and it has yet to be determined whether its use on a large scale will lead to an undue proportion of false-positive reactions. Possibly a minor source of confusion to diabetic patients is the fact that with this method a negative test is yellow (the original color of the paper) and a strongly positive test a dark blue or blue green, while with the copper reduction methods a blue color is negative and a yellow strongly positive. The necessity for accurate timing and the difficulty of distinguishing between different grades of glycosuria by the paper method are considered by some to be disadvantages, but these may well be offset by its great convenience.

INTRAVENOUSLY GIVEN AMINO ACID AND FAT SOLUTIONS

To the Editor:—*What is the value of intravenously given amino acid solutions? Is this form of amino acid metabolized to protein in the body? Is the difficulty in the production of solutions of fat for intravenous fusion due to the fact that proper emulsions cannot be obtained, and have ultrasonics been employed?*

M.D., Ohio.

Answer.—The intravenous administration of amino acids is important when the protein requirements of the body cannot be met by oral feeding. When bodily requirements are not supplied, the organism is forced to live on its own tissues. Amino acids for parenteral administration, available commercially as hydrolysates or mixtures of pure amino acids, can be effectively utilized in repairing or building tissue if the caloric requirements of the body are supplied concomitantly. The main difficulty in providing fat emulsions for parenteral use is the fact that the emulsions are likely to develop pyrogenic properties. Ultrasonics have been employed, but they are not effective in improving the stability of the emulsion.

TOXICITY OF INSECTICIDES

To the Editor:—*A patient held a dog while her husband sprayed it with insecticide. She inhaled some of the insecticide and shortly afterwards developed headache and symptoms suggestive of an acute brain syndrome. In spite of therapy she became comatose and died within 24 hours. Postmortem examination revealed no cause of death. The ingredients contained in the insecticide were as follows: pyrethrins, 0.51%; piperonyl butoxide, 0.512%; rotenone 0.256%; and other cube extractives, 0.472%. Is it possible that inhalation of any of these ingredients could be fatal? What are the antidotes?*

M.D., Florida.

Answer.—The ingredients in this insecticidal mixture are plant products, with the exception of the synergist, piperonyl butoxide. Botanical insecticides of the types described are capable of producing a fatal hypersensitivity reaction, but the occurrence of such a reaction is rare. The synthetic synergist has a low order of toxicity. There are no antidotes for untoward reactions to the above chemicals, and treatment, when required, is symptomatic and supportive.

CHOREA GRAVIDARUM

To the Editor:—*Please discuss the relation between pregnancy and hereditary chronic progressive chorea with mental deterioration (Huntington's chorea). I have a patient who had chorea (St. Vitus dance) and was told that the chorea was likely to recur with pregnancy.*

Robert J. Dickinson, M.D., Ridgway, Pa.

Answer.—Greenhill (Obstetrics, ed. 11, Philadelphia, W. B. Saunders Co., 1955) says: "Chorea gravidarum occurs in about one of every 3000 pregnancies and may recur in the same patient in subsequent pregnancies. It is closely associated with rheumatic infection. Its onset may be abrupt and severe, accompanied by a toxic-delirious psychosis. Of the 951 cases collected by Willson and Preece, more than 50 per cent of the women gave a history of having had chorea previously; however, there is no great danger of a recurrence during pregnancy in women who had the disease in childhood. Most authorities believe that interruption of pregnancy cures chorea; hence, they advocate therapeutic abortion if the patient's condition becomes worse in spite of conservative therapy. I believe that it is rarely necessary to interrupt pregnancy for chorea. The treatment of chorea during pregnancy is the same as in the nonpregnant state. Local anesthesia should be used for delivery whenever possible."

INTERVAL BETWEEN DPT IMMUNIZATIONS

To the Editor:—*Often through oversight DPT (diphtheria and tetanus toxoids and pertussis vaccine combined) immunization is not completed on the recommended four-to-six-week interval schedule. Is any one of the following patterns effective in producing immunity: (1) Long interval (6 to 12 months) between first and second injections with proper interval for the third; (2) proper interval between first and second injections and a long interval (6 to 12 months) between second and third; and (3) both intervals extended 6 to 12 months?* *Lawrence H. Lief, M.D., Jamesburg, N. J.*

Answer.—The generally accepted schedule of three doses of DPT injected at intervals of four to six weeks is designed to give the maximum amount of protection in the minimum amount of time. Equally high levels of immunity ultimately will be achieved after injection of DPT at greater intervals, such as those suggested in the three patterns described by the inquiring physician, the only difference being in the length of time required for the child to become immune.

HEARING HEART-LIKE SOUNDS

To the Editor:—*A physician, aged 74, complains of hearing a chest sound without the use of a stethoscope. It resembles a pericardial friction-like sound or musical whistling. It is completely synchronous with heart action and does not seem to proceed from one special part of the chest. It is most disturbing while he is in bed and when he changes position. Examination revealed that the heart is not enlarged, fluoroscopy is normal, and the only abnormal sound is a grade 2 murmur. The blood pressure is normal. Is this sound cardiac in origin, or aural? Is this common?* *M.D., Connecticut.*

Answer.—If the sound cannot be heard by an examiner who is properly trained to hear such sounds, it is altogether likely that the sound has its origin in the ear. It is not uncommon to find that a tortuous vessel impinges on some portion of the auditory apparatus and produces a noise. Most commonly this is described as a buzzing in the ears, but not infrequently it seems to the patient to have its origin elsewhere. If the patient's cardiovascular system is normal for his age, this phenomenon need cause no concern. In any event, there is little that may be done.

SEQUELA OF TRANSURETHRAL PROSTATECTOMY

To the Editor:—*A 70-year-old patient had a transurethral prostatectomy for benign hypertrophic prostatitis seven months ago. Complications included severe hemorrhage three weeks after the operation, two light hemorrhages two weeks later, and purulent infection by* Escherichia (Bacillus) coli, *with several relapsing crises for three to four months. The patient has also had lack of ejaculation until the present time. Is this a result of an obstruction of the ejaculatory ducts?*

A. A. Bernardo, M.D., Philadelphia.

Answer.—It is the rule rather than the exception that patients who have had a transurethral prostatectomy do not have external ejaculation after intercourse. The lack of ejaculation is not due to an obstruction of the ejaculatory ducts, but to the inability of the fascial muscular or mechanical action of the prostate in throwing the ejaculated seminal material out through the urethra and the external meatus at the time of crisis.

PLATELET COUNT FROM STAINED BLOOD SMEAR

To the Editor:—*How does a technician make an estimate of the platelet count from the routine stained blood smear?*

W. L. Martin, M.D., Romeo, Mich.

Answer.—The smear must be uniform and should be sufficiently thin so that the red blood cells can be counted as individual units. Use a diaphragm in the ocular or oculars, so that the field of observation is relatively restricted. This can be readily done by inserting between the two lenses of the ocular a piece of opaque material with a hole in it. Count in a number of fields the ratio between red blood cells and platelets. It is sufficient for a rough estimate to count about 200 red blood cells. Having determined this ratio, simply count the platelets in 10 or 20 additional fields without counting the red blood cells. With the ratio already known, and knowing, of course, the red blood cells, one can estimate the number of platelets with a good approximation. Experienced technicians can obtain a similar estimate by simply scanning a number of fields, as they observe other variations in the stained smear.

URINALYSIS

To the Editor:—*In routine hospital procedures the urine is collected between 5 and 7 a. m., and its examination in the laboratories may be done about 10 or 11 a. m. How exact is the report of the erythrocyte count and the leukocyte count? Are the cells dissolved during this time? Is the report that bacteria are seen of any significance in urine that has been standing in a hot environment for several hours? What kind of preservative should be added to urine at the time of collection?* *Erwin Leonhardt, Clayton, Mo.*

Answer.—It would seem that the urinalysis described is carried out about as promptly as is usual in most hospitals. Probably there is no significant loss in cells. Bacterial growth taking place in urine standing in a hot environment may be of significance if the specimen has been collected in a manner that avoids contamination; a catheterized specimen collected in a sterile container is a culture medium in which bacteria will multiply. The best preservative is refrigeration. A crystal of thymol may be used as a preservative. Textbooks suggest others that have been used, not too satisfactorily.

HOSPITAL STAFF BYLAWS

To the Editor:—*Where might I find a draft of a "model" set of bylaws governing the medical staff of a small (25 bed) rural community hospital?* *M. B. Jarman, M.D., Hot Springs, Va.*

Answer.—There are no "model" bylaws, rules, and regulations now published and up-to-date specifically for medical staffs of small rural community hospitals. In addendum 5, page 309, of "The Medical Staff in the Hospital" by Ponton (ed. 2, Chicago, Physicians' Record Company, 1953), however, "model" bylaws, rules, and regulations for medical staffs of hospitals of 50 beds or less are shown. These could be used, provided they are amended to conform to more recent recommendations regarding medical staff committees, attendance at meetings, and consultations. A guide to the wording of such amendments may be found in the "Principles for Establishing Medical Staff Bylaws, Rules and Regulations" published by the Joint Commission on Accreditation of Hospitals, 660 N. Rush St., Chicago 11. It should be emphasized that "model" bylaws should be modified to meet the individual hospital's needs.

STOMATITIS AND VAGINITIS DURING MENSTRUATION

To the Editor:—*A married woman, 28 years of age, each month at menses develops ulcerative stomatitis and glossitis and acute ulcerative vaginitis, also some dermatitis. She has visited many doctors. She gets much relief from taking vitamin B, but still develops the same symptoms. Have you any further suggestions on diagnosis and therapy?*

Lorne W. Mason, M.D., Evanston, Ill.

Answer.—There are cases in which unusual symptoms that develop just before menstruation yield to the therapy generally administered for premenstrual tension. Therefore, in addition to the use of vitamin B, which does give relief to this patient, other therapy should be added. Two popular forms of therapy are ammonium chloride, 0.6 gm. three times a day after meals for about 14 days before the expected onset of menstruation, with restriction of salt, or a 5-mg. tablet of testosterone propionate for sublingual or buccal administration daily for about 10 days before menses begin.

SUBJECT INDEX

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence, "ab," abstracts, the asterisk (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word with the following exceptions: Foundations, Lectures, Moving Pictures, and Prizes, under "F," "L," "M," and "P" respectively. "Book Reviews," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For the author index see page 42.

groups in peptic ulcer, [Brown] 835—ab, (ABO) [Buckwalter & others] *1215; [Clarke] 1571—ab
groups in pernicious anemia and duodenal ulcer, United Kingdom, 1490
Hypogammaglobulinemia. See Gamma Globulin
BLOOD—Continued
in rubella diagnosis, [Hillenbrand] 603—ab
iodine level during pregnancy, 939
iodine (protein-bound), drugs disturbing test, 1582
iron in visceral leishmaniasis, India, 1647
irradiation, ultraviolet, for run-down condition? 1350
lipid changes after nicotinic acid in hypercholesterolemia, [Parsons] 68—ab
lipid levels, Israel, 423, (correction) 677
lipids alimentary lipemia in coronary disease, United Kingdom, 1177
lipids and coronary arteriosclerosis, [Adlersberg & others] *619
lipids in arteriosclerotic heart disease, beta sitosterol effect on, [Farquhar] 525—ab
lipids modified by sitosterol in atherosclerosis, [Best] 1577—ab
lipoproteins high in progeria, [Rosenthal] 1667—ab
lipoproteins in normal and arteriosclerotic patients [Jencks] 1331—ab
pepsinogen in peptic ulcer and stomach disorders, [Hoar] 520—ab
phospholipids, age, sex, and coronary arteriosclerosis, [Adlersberg & others] *619
picture, abnormal, caused by paint removers? 1099
Platelets See also Purpura, thrombopenic
platelet antibodies, identification and significance, [Tullis] 1182—ab
platelet count from stained smear, 1676
Poliomyelitis Antibodies in See Poliomyelitis
Protein See also C-Reactive Protein, Gamma Globulin; Globulin, Poliomyelitis Immune Globulin, Properdin, Radio-Iodinated Serum Albumin
protein changes in subacute thyroiditis, [Stemmermann] *31
proteins, hypoproteinemia, France, 1252
proteins in tuberculosis of lung, United Kingdom, 60
proteins low in copper deficiency in infants, [Sturgeon] 1193—ab
proteins, paper electrophoresis in pregnancy, India, 1648
proteins, transient dysproteinemia in infants new syndrome, [Ulstrom] 1262—ab
prothrombin low from anticoagulants, vitamin K_1 for, [Cosgriff] 237—ab
prothrombin test, effect of bishydroxycoumarin on, (reply) [Garb] 63—C
pyruvic acid in kidney disease and uremic coma, [Kleeberg] 78—ab
quinidine in converting chronic atrial fibrillation, [Sokolow] 1570—ab
sedimentation rate after splenectomy, 1673
sedimentation rate, index of rheumatoid arthritis activity, [Lansbury] 68—ab
sedimentation rates, Westergren technique, 1674
sugar See also Diabetes Mellitus
sugar, amino acid and glucose ingestion effect on, [Mellinkoff] 1096—ab
sugar, carbutamide lowers, (Canada) 57, [Constam] 71—ab (severe hypoglycemia in diabetics) [Bendfeldt] 1263—ab
sugar, hyperglycemia after chlorpromazine therapy, [Hiles] 1651—C
sugar, hypoglycemia from metastasizing insulinoma, [Shaw] 838—ab
sugar, rapid estimation with Tes-Tape, [Seltzer] *1234
sugar, N-1-sulfanilyl-N-2-n-butylcarboamide lowers, [Garattini] 525—ab
sulfhemoglobinemia [Harsløf] 72—ab
test negative with skin test positive for histoplasmin, diagnosis, 1509
thromboplastin-antecedent deficiency, hemorrhage from [Henry & others] *727
tocopherol and erythrocyte hemolysis in hydrogen peroxide [Nitowsky] 1092—ab
Transaminase See Transaminase
Types See Blood groups
volume, radioactive iodinated serum albumin to determine, [Marshall] 928—ab
zinc in Laennec's cirrhosis sequential analysis, [Vallee] 1081—ab
BLOOD PRESSURE
control in sitting position and in hypotensive anesthesia antigravity suit in, [Gardner & Dohn] *274
in American and foreign students [Szent-Györgyi] 141—ab
increased, fails to induce arterial and arteriolar necrosis, [Johnston] 254—ab
measurement in obese persons, [Trout & others] *970
Portal See Portal Vein
BLOOD PRESSURE, HIGH
after nephrectomy and extrarenal urinary surgery, [Rallo] 246—ab
after pre-eclamptic toxemia, familial hypertension in etiology, [Browne] 1575—ab

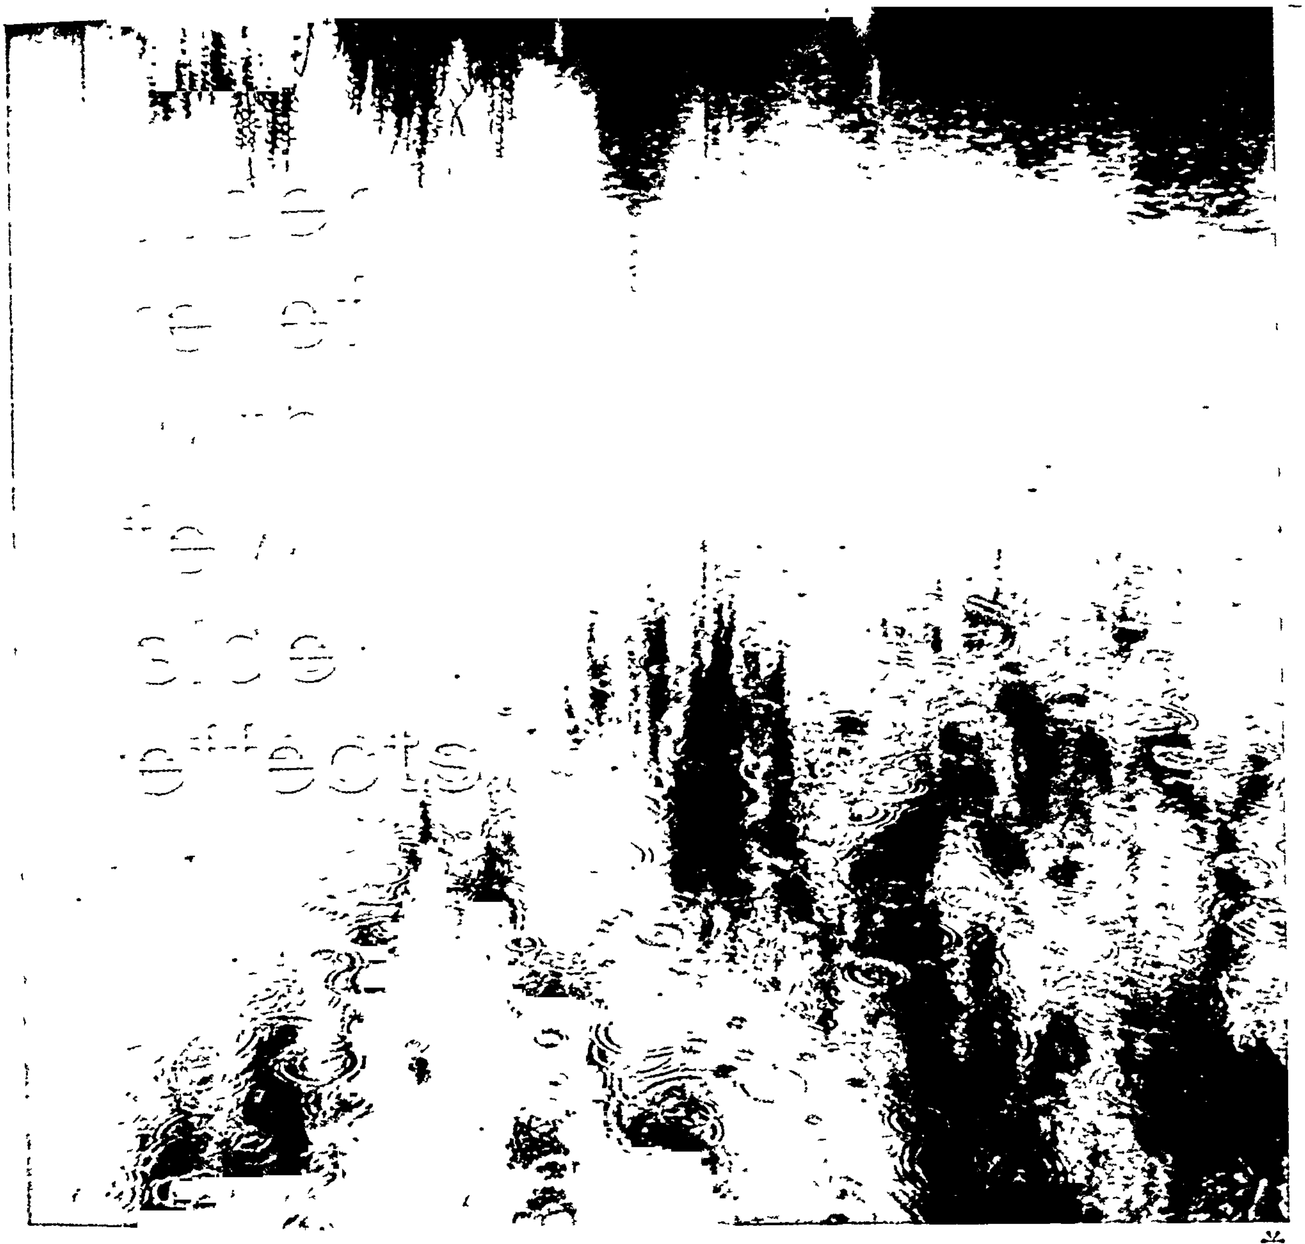
CLINICAL MEETING: October 20, 1956



PATHILON*

TRIDIHEXETHYL IODIDE LEDERLE

PATHILON is well tolerated in orally given doses and provides not only prompt clinical symptomatic relief but also effective inhibition of painful spasm at the ulcer site. Important to many patients, PATHILON is relatively inexpensive.

PATHILON is particularly useful in ulcer treatment because its peripheral atropine-like actions are associated with few side effects.[1] Side effects, if any, are usually not severe enough to warrant discontinuance of the drug.[2]

Recommended in the treatment of peptic ulcer, gastric hyperacidity and hypermotility, gastrointestinal spastic conditions such as spastic and irritable colon, functional diarrhea, pylorospasm, and hypermotility of the small intestine not associated with organic change.[3]

Available in three forms; *tablets* of 25 mg., plain (Pink) or with phenobarbital, 15 mg. (Blue), and *parenteral,* 10 mg./cc.—1 cc. ampuls.

1 *Evaluation of Drugs in the Treatment of Peptic Ulcer* by J M Ruffin, M.D; D Cayer, M D, J S Atwater, M D, and B G Oren, M D Exhibit at A.M A. Meeting, Atlantic City, June, 1955

my favorite story

In this space will be published anecdotes submitted by physicians concerning their practice or people in general. Contributions for "My Favorite Story" are welcome.

Jones had just made a killing on the stock market and now associated with new friends on a French luxury liner.

He wanted to show them how smart he was by ordering dessert from the foreign language menu. The waiter who took the order was astounded but went to fill his request and came back with a whole roast pig with an apple in its mouth.

Jones snatched the fruit from the pig's teeth.

"You know," he said smiling to his friends. "It's a funny thing, but this is the only way I like apples."

♣

how it started

"Not worth a rap" does not refer to knocking the knuckles. In the language of a few hundred years ago it meant literally a thing of no value, for the allusion is to an 18th century Irish coin called a rap, worth about half a farthing, the equivalent of a quarter of an American cent.

♣

The "Roman salute," invented by D'Annunzio, which became also the German salute, was copied from some statue or fresco. He forgot that in ancient Rome citizens greeted each other by shaking hands. Only slaves made the sign adopted by the subjects of Mussolini and Hitler.

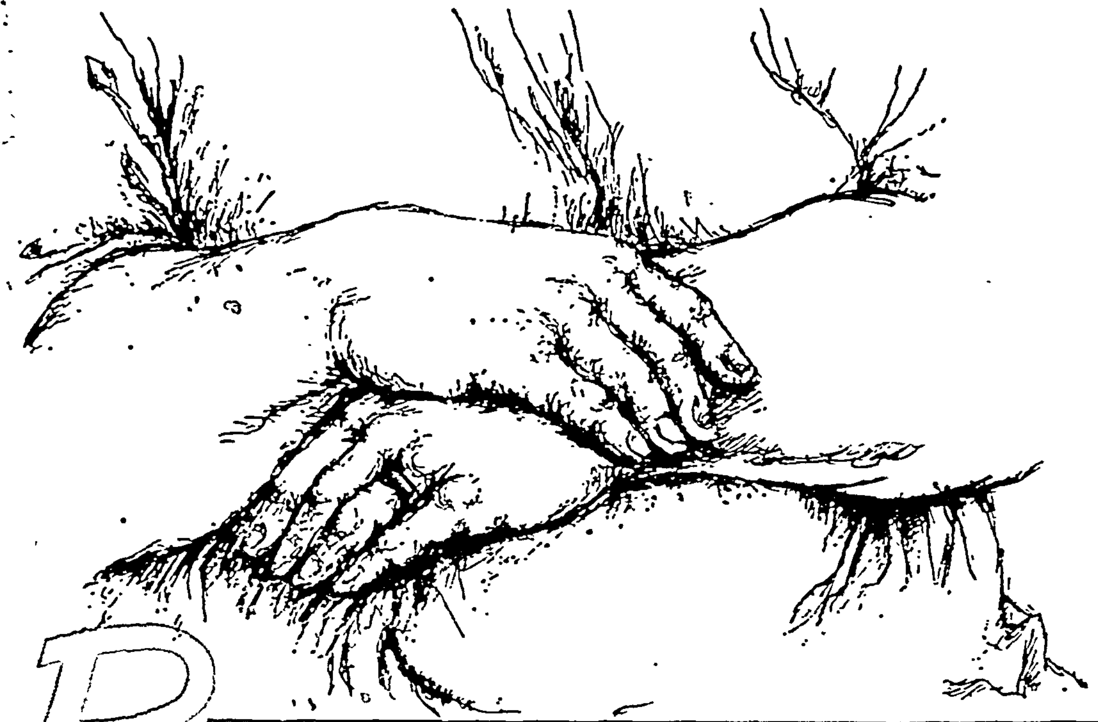
Doctor—it's up to you

to treat Obesity as a serious medical problem



RESYDESS

...able adjunct to obesity management

Far from being a subject for comic cartoons, obesity is recognized as an infamous contributor to a wide range of degenerative and organic diseases. Only you—employing weight-control agents such as dual-powered RESYDESS—can wean patients from excessive ingestion of food.

RESYDESS strikes at underlying causes of obesity:

1. It quells hunger and elevates the mood through an effective appetite-depressant. *dl*-Desoxyephedrine Hydrochloride.
2. It relieves emotional stress and anxiety tension believed by many to be a reason for compulsive eating, through a potent tranquilizer—Reserpine.

Tandem action of the teamed ingredients successfully checks the desire for excess food and simultaneously keeps the patient calm but alert.

Each RESYDESS tablet contains:
Reserpine............................0.1 mg.
dl-Desoxyephedrine Hydrochloride....8.0 mg.

A new and completely up-to-date 2nd Edition of the popular and respected

Handbook of DIFFERENTIAL DIAGNOSIS

By Harold Thomas Hyman, M.D.

Highly successful and enthusiastically received in its first edition, "The Handbook of Differential Diagnosis" is now even more complete, practical and easy to use. In this new edition, all data has been brought up to date and a great deal of new material added. It indexes more than 3200 entries, ably organized for quick reference. And more than 1200 analyses on differential diagnosis are cross referenced.

Throughout this exceptionally useful book, Dr. Hyman's discussions give emphasis to: conditions most frequently found in general practice; problems of the living patient; and physiologic derangements.

DIFFERENTIAL DIAGNOSIS is comprehensive. Essential information is easy to find, easy to use. The writing is crisp, concise.

New sections include: Chest and Precordial Pain, Cyanosis, Fatigue, Food Poisonings, Head Injuries, Kidney Function and Portal Hypertension.

Here is a vast wealth of useful information . . . a dependable source of help in your practice.

TONICS AND SEDATIVES *(Continued)*

Among the ancient Greeks there was a class of men who learned how to make themselves welcome at the tables of rich men by providing dinner entertainment of a flattering nature.

To such men was applied the term "parasitos," made up from the prepositions "para" meaning beside and "sitos" meaning food.

The term was translated into the Latin as parasitus and into English as parasite.

◆

"Caesarean operation" has no relation to the birth of Julius Caesar. The term goes far into antiquity, and the operation is supposed to have been performed by early Greeks. The word "caesarean" derives from the Latin past participle "caesus" from "caedere" meaning to cut.

◆

quotes of the week

A young man went to see a lawyer but told him there would be no fee paid unless the lawyer felt sure there were grounds for legal action.

Then he gave the lawyer a detailed account of the trouble.

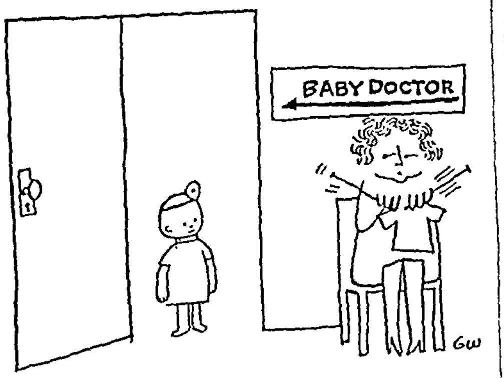
"Good Lord, the case is airtight!" shouted the lawyer. "The other fellow hasn't a leg to stand on. My advice is $50, and for an additional $100 retainer I will start suit."

"No," said the young man. "You'd better not."

"But why?" demanded the lawyer.

"Because I gave you the other fellow's side."

◆



◆

Smith used to play cards with the boys every Thursday. Then he got married.

Three weeks later he showed up again. The boys were naturally curious about his wedded bliss.

"Does she feed you well?" they asked.

"She gave me chicken three times last week and three times this week," Smith said proudly.

"Then you've no cause to complain?"

Smith's face dropped.

"Yes, I do," he said. "It was the same chicken."

◆

"Speeches are like babies—easy to conceive and hard to deliver."

BONADOXIN®

(BRAND OF MECLIZINE DIHYDROCHLORIDE. PYRIDOXINE HYDROCHLORIDE)

stops morning sickness ...often "within a few hours"[1]

Fifteen investigators have now confirmed BONADOXIN's efficacy. In 287 patients treated for nausea and vomiting of pregnancy, BONADOXIN was "of great benefit in 90.8% of the cases." Complete relief was often afforded "within a few hours."[1]

Each BONADOXIN tablet contains:

Meclizine HCl	25 mg.
Pyridoxine HCl	50 mg.

Mild cases: One BONADOXIN tablet at bedtime. Severe cases: One at bedtime and on arising. In bottles of 25 and 100, prescription only.

TONICS AND SEDATIVES *(Continued)*

The gambler was delivering a monologue:

"For three nights straight I dreamed about salami, bolony, and liverwurst. Is that a hunch, or isn't it? I go to the track and in one race three horses by the names of Salami, Bolony, and Liverwurst are running. So I bet all three to win."

At this point a friend interrupted. "Which horse won?"

"A long shot by the name of Cold Cuts."

♣

A man walked into a restaurant, ordered a cup of coffee, and then proceeded to put 20 heaping spoonfuls of sugar in the cup. Then he sipped daintily at the contents.

"Why don't you stir it?" the restaurant owner asked angrily.

"Why should I? I don't like it sweet."

♣

She was one of the new rich, and she didn't hesitate about letting her friends know.

One day she got a jeweled wrist watch, and when one of the girls asked her the time, she said: "It's exactly two emeralds past the diamond."

♣

"To be positive is to be mistaken at the top of your voice."

♣

"It's a great kindness to trust people with a secret. They feel so important while telling it."

♣

"A smoothly running engine makes little noise and yet produces great power."

♣

"Facts are stubborn, but statistics are more pliable."
